2. Improvement of Production Conditions, Strengthening of Ability to Withstand Disasters, and Promotion of a Benevolent Cycle in the Ecological Environment. Experiences from everywhere have shown that doing a good job of cottonfield capital construction to improve water, soil, and fertility conditions for production are key measures in realizing consistently high cotton yields. A very important reason for Ciqi County's high cotton output in the 1960's was adherence to a farming system that used superior varieties, "deep ditches and high ridges" in cottonfields, good drainage and irrigation conditions, a green manure area stabilized at more than 80 percent, and reasonably spaced planting of spring blooming varieties. Subsequently, under the influence of "leftist" ideology, some communes and brigades filled in streams and leveled ditches, grew little green manure, and planted spring blooming varieties closely. The soil became leathery and foliage shading was serious, causing a vicious cycle in the ecological environment. Consequently, much

attention must be given regulation of water and improving the soil in adherence to and revival of traditional planting techniques using "deep ditches and high ridges," equitable planning of the preceding crop, the growing of plenty of green manure, and doing a good job of purification and rejuvenation of cotton varieties to hasten regeneration of fine varieties.

3. Scientific Use of Fertilizer in Accordance With the Laws of Growth and Development of Cotton, Doing a Good Job of Handling the Relationship Between Advancing and Retarding. One of the reasons for reduced cotton output by some communes and brigades during recent years has been improper management of fertilizer and water. In violation of the laws of growth and development of cotton, blind fertilization has been done, with too little organic fertilizer used with the result that an imbalance has been created between vegetative growth and reproductive growth. The experiences of many high yield units attest that in handling the relationship between advancing and retarding, only when plenty of organic fertilizer is used and scientific fertilization is done will cotton grow steadily without premature decline to produce consistently high yields. After increasing the soil's basic fertility, in recent years the Ningwei Commune in Xiaoshan County promptly fertilized for seedling growth, fertilized again for control of squaring, again for cotton boll formation, and also fertilized with ashes and chemical potash. In addition, it did a good job of disease and insect monitoring and reporting, and prevention and control work. It was able to steady and lengthen the squaring period and stabilize the cotton boll formation period to prevent premature deterioration, harvesting numerous and large cotton bolls for yields averaging 126 jin per mu during the past 4 years.

In order to bring about a rise in cotton production this year, cotton growing area production responsibility systems have to be further perfected, planting being done in accordance with state plan as well. In the course of investigation during the previous period, it was discovered that some communes and brigades in cotton growing areas were preparing to reduce the planned cotton growing area. This problem should arouse serious attention. Cotton is a good that bears on the national economy and the people's livelihood. Account must be taken of the situation as a whole for proper implementation of agricultural production programs. While positively not relaxing grain production, cotton production should be actively taken in hand to win a bumper cotton harvest this year.

OVERALL STATUS REPORT ON COMMUNE ENTERPRISES GIVEN

Hangzhou ZHEJIANG RIBAO in Chinese 5 Feb 82 p 1

[Article by Reports Unit, Provincial Commune and Brigade Enterprises Administration: "Total Annual Income Amounts to Almost One-Half Gross Income From the Three-Tier Rural Economy. Province's Commune and Brigade Enterprises Continue Healthy Development. Paid 300 Million Yuan in Taxes to State Last Year. Average Income Increase of 35 Yuan Per Capita of Agricultural Population"]

[Text] In 1981, Zhejiang Province's commune and brigade enterprises carried out CCP Central Committee programs for the national economy of further readjustment, winning continued, healthy development. Gross income amounted to more than 5.8 billion yuan, a 20 percent increase over the previous year, with gross output value of commune and brigade industry amounting to somewhat more than 5.3 billion yuan. Thus, commune and brigade enterprise earnings amounted to about 49 percent of gross earnings from the three-tier rural economy of the province. Gross output value of commune operated industries amounted to 13.8 percent of the province's gross industrial output value.

In 1981 all levels of CCP committees and government in the province earnestly strengthened leadership over commune and brigade enterprises to assure smooth performance of readjustment programs. Departments in charge of commune and brigade enterprises, and commune and brigade leaders everywhere established a conception of the situation as a whole, and proceeded from the needs of the country and the markets, and from local realities and possibilities to carry out diligent readjustment and reorganization on the basis of the individual situation in each kind of enterprise. For the 40 percent of the province's commune and brigade enterprises whose production orientation was on the right track, for which sources of supply for raw materials existed, and for which markets existed for their products, the watchword was "up," [management] with efforts centering on reorganization of enterprise management and increasing product quality. Many enterprises turned out "hot-selling" goods that met advanced provincial and national standards. For electro-mechanical enterprises whose goods could find no markets, then the watchword was "conversion," with consolidation and upgrading being done in the course of conversion of production. In Ningbo Prefecture, for example, more than 2,300 electro-mechanical enterprises operated by communes and brigades accounted for 37 percent of the prefecture's total number of commune and brigade-operated enterprises. They had converted "heavy" [industrial enterprise] to "light," and used "rural people" rather than "city workers" in an effort to readjust the direction of service enterprise and change in product composition. Last year, these enterprises' output value amounted to more than 380 million yuan, a 40 percent increase over the previous year. For the approximately 5 percent of commune and brigade enterprises in the province whose products could find no markets or sources of supply of raw materials, or which consumed large quantities of energy or seriously polluted the environment, some were resolutely "closed" or "suspended." Attention was focused on "up, conversion, and down," [management, flexibility and basic level of production] so that the province's commune and brigade light industries and heavy industries would have coordinated development. Last year's output value from commune and brigade light industries as a proportion of gross output value for all commune and brigade enterprises in the province rose from the 51 percent of 1980 to 64 percent. Output value commune and brigade industry consumption goods used in the daily lives of the people for food, clothing, daily use, or living amounted to about 80 percent of gross output value.

Healthy development of commune and brigade enterprises has brought increased benefits for the country, for rural commune and brigade collectives, and for individual commune members. In 1981, commune and brigade enterprises in the province paid a total of about 1.1 billion yuan in compensation to labor or for distributions to production teams, an average of 35 yuan per person engaged in agriculture in the province. The province's commune and brigade enterprises paid revenues of 300 million yuan to the state, a 50 percent increase over the previous year.

TITLE: "Ecological Environment and Utilization of Natural Resources in Huanghe Delta"

SOURCE: Dalian ZIRAN ZIYUAN [NATURAL RESOURCES] in Chinese No 1, Mar 82 pp 18-25

ABSTRACT: The estuary of Huanghe includes the 4 parts of the modern estuarial delta, the lowlands of the lower reaches of Tuhai and Majia rivers, the lowlands of the lower reaches of tributaries, and the shore areas. This region of about 10,600 km^2 is a part of the northwestern plain of Shandong, where the unstable ecological system constitutes the important problem in the utilization of its natural resources. The vegetation is undergoing various stages of changes and aside from such factors as reclamation, grazing, and industrial pollution, these changes are closely related to the variable saline contents of the soils. The terrain and the dynamic state of the ground water have a very great effect on the salinization and desalinization of the soils. During tidal ingressions and channel changes of Huanghe, a change of vegetation follows. Shengli oil wells are extensively distributed in this region. Everyday, 72 thousand tons of waste water containing petroleum and phenols is discharged to alkalize the soils and destroy the plants. With the rapid change of the environment, the inhabitants have gradually moved away and the development of the

[continuation of ZIRAN ZIYUAN No 1, 1982 pp 18-25]

natural resources and their protection have become increasingly difficult as well as urgent. The authors offer suggestions in the following 7 ways to harmonize the region's ecological system: (1) Maximum utilization of the silt resource of Huanghe; (2) Introducing and experimenting with Damicao [a weed of Genus Gramineae] and bluish dogbane [Apocynum venetum]; (3) Afforestation to reconstruct an ecological balance; (4) Readjusting the swine-dominated animal husbandry structure in favor of the development of grass-eating animals;(5)Coordinating agriculture with forestry to start a large scale construction of firewood and charcoal producing forests; (6) Emphasizing good management of State-operated farms to establish a foundation for gradual creation of various forms of joint enterprises of agriculture, industry, and commerce;(7) Strengthening research studies of ecology, geological and geographical sciences, and biological sciences of the Huanghe estuarial region. Each of the above aspects is discussed in some detail.

SCIENTIFIC FARMING SAID SEQUEL TO PRODUCTION RESPONSIBILITY SYSTEMS

Beijing RENMIN RIBAO in Chinese 26 Apr 82 p 5

[Article by He Kang [0149 1660]: "Agricultural Modernization and Reliance on Science To Develop Agriculture"]

[Text] Basic Characteristics and Survey of Development of Modern Agriculture

The fundamental characteristic of modern agriculture is the application of modern science and technology plus investment of substantial material and energy to gradually replace traditional agriculture founded on experience with modern agriculture founded on science. Generally speaking this means making production techniques scientific, mechanizing the tools of production, and socializing the organization of production.

First, making agriculture scientific. This is the wide application of agricultural production of all sorts of advanced scientific techniques. Agricultural science is a scientific system that is strongly all encompassing and very broad in scope. It includes various aspects upward to astronomy, downward to geology, and sideways to biological and human activities. Steady development of agricultural science makes agricultural production steadily rise to new levels. For example, in the field of genetic breeding the use of hybrid heteroses to breed short stemmed, lodging resistant and disease and insect pest resistance high yield varieties plays a tremendous role in increasing output. During the 1930's corn yields in the United States were 200 jin per mu, but beginning in 1936 hybrid corn varieties were universally extended to cultivation, and now yields average 950 jin per mu. The world's so-called green revolution has resulted primarily from the extension to cultivation of superior varieties of Mexican wheat and Philippine rice. Formerly neither of these countries was self-sufficient in grain, but with the extension to cultivation of fine varieties plus the use of irrigation and chemical fertilizer they have now become self-sufficient. In the realm of livestock, Danish lean pork long white hogs have one more set of ribs than common hogs, and Dutch Haisaikesi [phonetic] hybrid chickens can produce 260 eggs annually, each egg averaging a weight of more than 60 grams. Speed of growth of hybrid poplar trees is double that of common varieties. Today throughout the world chemical fertilizers are developing in the direction of concentration, complexity, slow release, and liquification. Emphasis is on comprehensive prevention and control of crop diseases and insect pests with the use of pesticides of high effectiveness, low toxicity, and low residualness to replace pesticides of low effectiveness, high toxicity, and high residualness. Only 1 gram per mu of a newly discovered Dalmation chrysanthemum fat need be used to remove insects. Herbicides are used for the elimination of weeds, and ways of avoiding plowing or doing little plowing are being used in farming to save one-third or more energy and to prevent erosion as well. These techniques are truly changing with each passing day.

Agricultural biology is now breeding a new technical revolution, principally in the several fields of photosynthesis, biological nitrogen fixation, and genetic engineering. For example in photosynthesis, right now the efficiency of most crops in using solar energy for photosynthesis is only 1 percent, and probably 2 to 3 percent for high yield crops. If the photosynthesis efficiency of plants could be raised 1 percent, agricultural outputs could be greatly increased. Another example is biological fixation of nitrogen. If rice and wheat were able to grow root nodules as soybeans do and fix nitrogen from the air, a large saving of nitrogenous fertilizer could be effected.

Second, mechanization. Mechanization has gone through a fairly long process in every country. The trend of development today is toward high horsepower for combined operations. The farm equipment pulled by a 100 horsepower tractor operated by a single person could complete furrowing, sowing of seeds, fertilization, and hoeing of weeds all at one time. Likewise the entire production process from field work and hauling to cleaning of grain, drying, storage, and processing are all mechanized.

A high degree of mechanization has also appeared in the mechanized raising of livestock and growing of crops. For example, in raising chickens, the feeding, watering, and clearing away of manure in chicken coops is all automatically controlled. One or two people can take care of more than 100,000 chickens.

Third, socialization of agriculture. From a basis of regionalization and specialized production, development has become a socialized and scientifically managed production system in which supply, production, and marketing are closely linked. The change is from a small but complete and self-sufficient natural economic traditional agriculture to a commodity economy of agricultural enterprises.

Socialization requires a process of formation. At the outset is a regionalization of production with the gradual formation, on the basis of local resources, soil, and climatic conditions, of locally concentrated production of certain major agricultural commodities. For example, in the American corn belt, wheat belt, and dairy cow and livestock belt, this process proceeded to specialized farms, with the formation of specialized chicken farms, cotton farms, and vegetable farms. After the 1950's further vocational specialization occurred. In agriculture, a large number of jobs are specialized such as the supply of seed being done by seed companies, hauling done by hauling companies, harvesting done by companies specialized in harvesting, and even the spraying of pesticides being done by special aircraft companies. The regionalization, specialization, and socialization of agriculture and the increasingly intensive scientific care are all products of the development to a certain stage of social productivity and a commodity economy. They play a tremendous role in equitable use of natural resources, the application of advanced science and technology, and in increasing benefits from production.

Scientificness, mechanication, and socialization are the three basic characteristics of modern agriculture. These three characteristics are mutually related and mutually advancing. What is their essential quality? Their essential quality is to found agriculture on modern science, to use modern science and technology and modern industry to equip agriculture, and to use modern economic science to manage agriculture. The goal is to create a high output, superior quality, low consumption farming, forestry, livestock raising, sideline occupation and fishery production system, and a fairly highly transformed and efficient agricultural ecological system that uses resources in a sensible manner and protects the environment in order to satisfy the needs of humanity.

It may be seen from the foregoing that agricultural modernization is a historical process of technical transformation and economic development whose ramifications are very broad and which is very strongly all encompassing. Thus, the modernization of agriculture is a comprehensive concept and a historical concept. It is also a relative concept. To speak of the modernization of agriculture in terms only of mechanization, of bringing all farmland under irrigation, and of electrification is, it is feared, too simple.

Because the national situation in each country differs, the road to modernization is also not entirely the same. There are more or less three kinds of roads to modernization in the world. One kind is that of countries with large amounts of land relative to population, with insufficient workforces and in which industry is very developed, such as the United States, Canada, Australia, and the USSR. The first step in their modernization of agriculture has been an emphasis on mechanization. Another kind of country is one such as Japan in which population is large relative to land, each person having only 7 fen of cultivated land. They emphasize biological and chemical techniques, use fine varieties and chemical fertilizers, and go in for the building of farmland. The third kind is found in some of the countries of western Europe such as France and Germany, which are industrially advanced and in which neither the amount of cultivated land nor workforces suffice. Consequently, they simultaneously develop both mechanization techniques and biological techniques. Actually, each country takes its own road to modernization on the basis of its own situation. It has its own emphasis, but it does not just do a single thing but rather coordinates techniques of all kinds for the gradual modernization of its agriculture.

Effectiveness of foreign agricultural modernization. First is a very great increase in labor productivity rate; second is a high commodity rate and high yields per unit of area. In addition, as a result of the development of production, the gap between city and countryside and the difference between industrial and agricultural earnings gradually narrows.

Problems in the modernization of agriculture abroad. Apart from the contradictions between capitalist private ownership and socialized production, and the disparaties between the poor and the rich, the main problem in agriculture itself is high energy consumption, high investment, and very great increase in costs. Furthermore, use of large amounts of chemical fertilizer and pesticides has brought about environmental pollution; irrational clearing of land and denudation of forests has also given rise to soil erosion and deterioration of the environment.

Many scholars believe that in future agriculture must turn toward greater reliance on science and biological techniques and strive for greater economic benefits rather than consume large amounts of energy and funds as has been done in the past.

Looked at in terms of development trends, the modernization of China's agriculture requires taking into account not only China itself but also taking account of the world. We cannot think only of our present; we must also think about our posterity. We must draw on the experience of others and learn from foreign experiences to avoid possible abuses.

Development of Agriculture Under the New Rural Situation Requires Reliance on Science

Development of agricultural production presently relies on policies and on science. Once agricultural production systems of responsibility have been substantially settled, the next step will be an emphasis on reliance on science. This is a change. Now that the situation in rural villages is good, peasants want science. In many places a mass fervor for the study and use of science has arisen. The building of China's agricultural production on a foundation of science is a first step in the gradual modernization of agriculture.

In proceeding from present day realities, agriculture's reliance on science requires emphasis on the following several tasks.

First is to do a good job of surveying agricultural resources and doing agricultural zoning, readjustment of the structure and patterns of agricultural production, and bringing a halt to the deterioration of the ecological environment. A good job has to be done in surveying natural resources such as soil, water, climate, and biology, and on socio-economic conditions followed by agricultural zoning and putting forward proposals about the production patterns of each area, of measures to increase output, and plans for development. Accumulated resources need to be inventoried and crop patterns properly laid out. This is a first step in agriculture's reliance on science; it is a basic task in the adaptation of general methods to local situations, in giving tailored guidance for production, and for gradually modernizing agriculture. Throughout the country 1,380 counties have begun zoning work, and 277 counties have turned in zoning reports. During the past few years, they have emphasized county zoning and surveys of soil and water resources as well as of key areas for development. The following have emerged through zoning requirements: first is the need to bring to a halt the destruction of resources and to put forward genuinely workable measures for their protection. Second is an equitable readjustment of the production structure and of crop patterns with development of economic diversification. Third is the need to come up with effective measures for increasing production right now; and fourth is to put forward proposals for long-range plans and a development scheme.

Second is to promote effective means of increasing production through adaptation of general methods to local situations. One way is with fine varieties. Fine varieties can usually increase yields by 10 percent. A system for breeding, reproducing, and promoting fine varieties should be established for the spread of existing fine varieties before 1985. Fine variety crop patterns should be regionalized, production should be specialized, processing should be mechanized and quality should be standardized. Another way is through scientific fertilization with the equitable readjustment of proportions of nitrogenous, phosphate and potash fertilizer. Currently probably 1 billion mu lacks phosphate and 300 million mu lacks potash. Were phosphate and potash production and imports to be increased and the methods of fertilizing improved, results obtained from fertilizer could be greatly improved. Another way is use of water. Most important is improvements in management for sensible use of water to take full advantage of existing water to increase output. A fourth way is plant protection. The make-up of pesticides has to be changed and farm machines for applying pesticides improved, with the spread of all encompassing measures for prevention and control. A fifty way is through research on techniques for farming, storage, processing, transporting, and marketing. with improvements being made on the basis of needs for development of production and economic diversification.

Third, serious attention must be given intelligent development of investment, and vigorous strengthening of agricultural education, scientific research and the extension of technology.

First a good job has to be done in agricultural education and training. First should be good running of existing agricultural schools. Second should be a good job of reforming primary school education. Rural middle and primary schools should increase their agricultural courses, some middle schools being converted to agricultural middle schools. Third should be a strengthening of cadre training, particularly leadership cadre training. In addition, outstanding middle age and young cadres should be selected to go to agricultural schools to improve their knowledge. Fourth should be a good job in peasant education with a good job done in county, commune, and production brigade peasant education.

Next is the need to readjust and augment agricultural research work. Today there is both a shortage of personnel, equipment, and funds for agricultural research and also duplication of courses and dispersal of forces. During the next few years, leaders should concentrate forces for readjustment and set a direction, tasks, and a cooperative division of labor for central government, provincial, and prefectural scientific research units, with the organization of attacks on key problems.

Still another need is to genuinely strengthen the work of spreading science and technology with emphasis going to the strengthening of county agricultural promotion forces. All jurisdictions should arrange, in order of priority, existing scientific and technical achievements, good experiences from other places, and technology used abroad and, on the basis of local needs, work up plans and do a solid job of promoting them little by little over a period of time. We also propose that each commune be able to gradually assemble three to five agricultural technicians who have graduated from higher or secondary technical schools to give intelligent assistance to communes and brigades on behalf of the country. Advocacy should be given the organization of technical service companies and peasant scientific farming societies to promote responsibility systems of technical contracting, and for energetic strengthening of publications, cinemas, broadcasts, exhibitions, and such activities for the popularization of science.

Fourth is energetic establishment of a huge red and expert agricultural science and technology cadre corps. It is hoped that leaders on all levels will attach serious importance to and do a good job with agricultural scientific and technical personnel, have confidence in them politically, give them support in their work, show concern for their livelihoods, and do a good job in evaluating, examining, and providing additional training for them as well as in returning agricultural technical cadres to their units. Last year Jiangsu Province made a planned evaluation of more than 10,000 of its commune farm science station and peasant technical personnel. More than 7,300 of them were found to meet secondary technical school standards as a result of testing, and they were issued certificates as well as a monthly technical stipend from the prefecture's public funds and from communes and brigades. This gave sudden impetus to rural science and technology work throughout Jiangsu Province, and rural youths felt this was something to strive for. This merits serious consideration by all jurisdictions.

BRIEFS

SIDELINE PRODUCT PROCUREMENT--As of the end of December, 1981, 52.43 million dan of cotton had been procured nationally. This was a more than 4 million dan increase in quantity procured over 1980, and it is anticipated that an additional approximately 3 million dan remains to be procured. Jute and amberi hemp procurement already totals 10.38 million dan for a 30 percent overfulfillment of plan. Flue-cured tobacco procurement amounts to more than 23 million dan, a 36 percent overfulfillment of plan. Light and textile raw materials, such as ramie, sun-cured tobacco, wool, sheepskin and silkworm cocoons also overfulfilled procurement plans. National procurement of tea in 1981, amounting to 5.43 million dan, reached an all-time high. Apple procurement was 360,000 tons more than during 1980, and more than 70,000 tons of citrus fruit was procured over that in 1980. [Text] [Shanghai JIEFANG RIBAO in Chinese 19 Jan 82 p 3] 9432

LOAN RECOVERY--A dispatch from Beijing dated 18 January reports issuance of numerous agricultural loans during 1981 by rural financial units in China, and a high recovery rate, with extremely good results being won. Preliminary statistics from the Chinese Bank of Agriculture show that during 1981 the Bank of Agriculture and credit cooperatives together issued 30 billion yuan in agricultural loans, 27.2 billion yuan of which they recovered, for a recovery rate of 91, an all-time high. BRIEFS

GRAIN MILLING SYMPOSIUM--Beijing, May 29 (XINHUA)--More than 100 foreign experts and 50 Chinese specialists are scheduled to attend an international symposium on grain milling and baking, according to the Ministry of Commerce. The symposium, jointly sponsored by the Chinese Ministry of Commerce and the Sosland Publishing Company of the U.S., will be held in the seaside summer resort of Beidaihe, east of Beijing, from September 2 to September 15. Topics for discussion at the symposium are: grain handling and preservation, train processing and flour milling, baked food production, and grain markets analysis. About 30 technical papers are expected to be submitted to the symposium and a technical exhibition will be held in conjunction with it. [Text] [OW291252 Beijing XINHUA in English 1228 GMT 29 May 82]

WATER PROJECTS--Beijing, May 29 (XINHUA)--Beijing has resumed construction on two major water diversion projects, part of the effort to ease the current water shortage resulting from sustained dry spells in the past two years, the Municipal Water Conservancy Bureau announced today. Construction on the projects began in 1970 but was discontinued later due to lack of funds. One of the projects being built in Yanqing County will divert an annual average of 100 million cubic meters of water from the Baihe River into the Guanting reservoir. The Guanting reservoir, which was built in the early 50's, is a major supplier of water for Beijing. Owing to the expansion of industry and agriculture and the dry weather, the amount of water stored in the reservoir is dwindling. The other project, now being build in Shunyi County, is expected to divert an annual average of 80 million cubic meters of water from the Chaobai River into Beijing's running water system, according to the bureau. It will mainly benefit the Beijing No 1 Heat and Power Plant, which consumes 250 million cubic meters of water a year. The plant will recycle the Chaobai River water to reduce its annual consumption from 250 million cubic meters to 50 million cubic meters. CONTROL OF PORK MARKET, BANNING OF MONOPOLIES EMPHASIZED

Fuzhou FUJIAN RIBAO in Chinese 10 Feb 82 p 2

[Commentary: "Banning 'Pig Monopolization'"]

[Text] The banning of "pig monopolization" by the people's government of Jianning County helps safeguard the policy of state purchases, stablize prices and protect the people's living standards. Jianning County has done the right thing and done it well. The control of the pork market by secondary dealers and its adverse effect on the fulfillment of purchase quotas was seen not only in Jianning County; there have been signs if it in other places as well. In some places, in fact, secondary dealers and pig monopolists are even more ruthless in slaughtering pigs and selling them at high prices, gravely interfering with purchase quotas and seriously affecting the stability of prices and the people's livelihood. We should give full attention to this matter.

Pigs are a class II commodity under the state plan and are an important food item for both the military and civilians. Party committees and governments at all levels should strengthen their leadership in this matter, educate the cadres and the masses to see the importance of the state and the state plan, and earnestly see to it that purchase quotas on pigs are fulfilled. In localities where purchase quotas have not been fulfilled, no one should be allowed to slaughter pigs and sell them on the market. Even in localities where purchase quotas have been fulfilled, only peasants should be allowed to slaughter their own pigs (or have others slaughter for them). No secondary dealers or speculators should be allowed to slaughter pigs and sell them at high prices. All violations must be punished. For pigs sold at negotiated prices by peasants who raised and slaughtered them themselves, government departments should prescribe a certain price range, and no one should be allowed to drive up prices. It has been shown in localities that have carried out these policies that not only have the purchase quotas on pigs been fulfilled well, but the market prices have also been stabilized. On the other hand, in localities where the leadership erroneously believes that the rural responsibility system of production has made it impossible to fulfill the purchase quotas on pigs, where the leadership is immobile, helpless and afraid to deal with the illegal slaughtering of pits and driving up of prices by secondary dealers and speculators, purchase quotas have been underfulfilled and market prices destabilized. It would be very dangerous to let this situation go on. All localities confronted with such a problem should follow the example of Jianning County and take vigorous steps to ban pig monopolization, regulate prices, and insure that purchase quotas on pigs are fulfilled.

NANPING CITY SETS UP PIG PRODUCTION BASES

Fuzhou FUJIAN RIBAO in Chinese 10 Feb 82 p 2

[Article by Guo Xunan [6753 8113 2344], Hong Zhenya [3163 2182 0068] and Yang Bin [2799 2430]: "Greater Pig Supplies, More Stable Pork Prices, Commodity Pig Bases Prosper in Nanping City"]

[Text] The commodity pig bases in Nanping City have been flourishing. Last year, these bases supplied 12,763 pigs to the city, accounting for 47.5 percent of all pigs supplied to the city from units below. These bases have contributed to increasing meat supplies to the city and to stabilizing meat prices.

A few years back, pig-raising in the city was developing very slowly. Every year, despite strenuous efforts, purchase quotas in pigs were hard to fulfill. For 7 months in 1977, no pork was available at all on the market, and people were greatly dissatisfied. To change this, the municipal party committee decided in 1979 to set up six commodity pig bases in suburban communes and brigades, such as Dongkeng and Xiqin. With the support of the province, prefecture and city, 43 pig sties were built, plus six processing warehouses, and one small reservoir, and some 385 mu of farmland were set aside for growing feed. The bases are put under the leadership of the communes and brigades where they are located, and are managed by capable cadres and responsible commune members assigned by them. The city's food company has the right to allocate the pigs. With pig-raising as the main production, all six bases maintain a diversified economy, with sheep, poultry and fish raising, plus 580 mu of hill land planted in orange, persimmon, pear and other fruit trees.

In the very first year they were established, the bases showed their worth by providing more than 4,000 pigs to the city, which accounted for 20 percent of the pigs supplied to the city from lower units. But all the bases ran a deficit every year. This was because in the first 2 years a great deal of effort went into capital construction, people lacked experience in management, and the distribution system was such that the stockmen all "ate from the same pot of rice," which dampened work enthusiasm. Some stockmen went back to farm work in the brigades. Starting this year, however, a system of responsibility has been introduced in the bases, bringing about an immediate change. The system consists of such features as fixed jobs and work norms, remuneration on the basis of production, and rewards combined with penalties. Contracts are signed between the bases and the stockmen providing for fixed work, fixed remuneration, fixed feed, fixed rate of mortality, fixed expenditures and fixed rewards and penalties. As more work gets more rewards, work enthusiasm rises along with a sense of responsibility about one's job. Instead of running deficits, the bases have begun to make a profit.

The bases play a positive role in stabilizing pork supplies and pork prices in the market. For the National Day holiday last year, the city's food administration requisitioned only 26 pigs from the countryside but more than 1,200 pigs from these bases, which insured a full supply of fresh meat for urban consumers during the holiday. The consumers were satisfied. The city's food company has also set up two additional stores selling fresh meat at negotiated prices. The stores get 30-40 pigs every day from the bases so they can sell fresh meat every day. In addition to supplying fresh meat to restaurants, these stores help stabilize meat prices on the free markets.

JIANNING COUNTY BANS PIG MONOPOLIES

Fuzhou FUJIAN RIBAO in Chinese 10 Feb 82 p 2

[Article by Jiang Jingzhang [3068 2417 4545], Jiang Changzhi [5592 7022 0237] and Wu Wenzheng [0702 2429 2973]: "Jianning People's Government Bans Pig Monopolies and Reinforces Market Regulation"]

[Text] Since the people's government of Jianning County took measures to reinforce market regulation and ban the "pig monopolies" in urban and rural markets, the number of pigs purchased by the state has increased and the price of pork has come down more than 20 percent.

To enliven its urban and rural markets, Jianning County allows commune members to put their pork on the free market after they have fulfilled the purchase quotas for pigs. But some pig dealers, having no licenses but aiming at exploiting the difference between fixed and negotiated prices, went all out to buy up commune members' pigs at high prices. They took advantage of the laxity of certain departments to monopolize the market and drive up the price of pork--from 1.30 yuan to 1.60 yuan, then to 1.80 yuan and even to 2.00 yuan per jin. The rise in pork prices drove up the price of other nonstaple foods, lowering the living standards and causing widespread resentment.

Pigs are a class II commodity important to military and civilian consumption and subject to purchase quotas. The leadership of the county people's government made a thorough investigation of the activities of the "pig monopolies" and decided that their monopoly of the pig market and control of pork prices must not be allowed to continue, the inertia and laxity of the leadership must be overcome, and effective countermeasures must be taken. A conference attended by leading members of commercial departments, industrial establishments, supply and marketing cooperatives, food supply depots and the communes was held to discuss ways to reinforce market regulation. Strong measures were adopted to ban all "pig monopolization" activities, allowing only commune members to market pork after they have fulfilled the purchase quotas. Since banning the "pig monopolization" activities, the number of pigs purchased increased sharply starting last November. By December, pigs purchased by the state and pigs supplied to higher level units exceeded quotas by 20 percent and 13 percent respectively. Market prices for pork went down from 1.60-1.80 yuan to 1.30-1.50 yuan per jin. The people were happy.

BETTER RESULTS FROM FEEDING HOGS COMPOUND FEED REPORTED

Lanzhou GANSU RIBAO in Chinese 2 Feb 82 p 2

[Article from "Grain and Oil Situation," published by Provincial Food Department: "Jiuquan Prefecture Actively Launches Compound Feed Production and Test Feedings. A Major Measure in Rapid Development of Animal Husbandry and Livestock Raising Industry"]

[Text] Jiuquan Prefecture grain departments have actively launched compound feed production and test feedings with the cooperation and support of units concerned, winning rather good results that will be promoted throughout the prefecture.

Last year, in coordination with commercial, farm machine, scientific and technical, and commune and brigade enterprise management units, Jiuquan Prefecture grain departments built five compount feed processing plants in Anxi, Jinta and Jiuquan counties in accordance with the principle of smallness paramount, collective investment paramount, semi-mechanization paramount and renovation paramount. As of the end of 1981, one site had gone into formal production, another site was running trial production, and the three remaining sites were installing equipment and would rapidly begin trial production and full production. In order to launch feeding with and promotion of compound feeds, the prefecture planned 19 separate compound feed test feeding sites. As a result of the test feedings, 13 compound feed formulas suitable for local use were preliminarily selected.

Judging from results of test feedings, use of compound feeds to raise livestock possesses the following advantages:

(1) Improved feed utilization rate. Following test feedings using compound feeds, for each jin increase in hog weight, consumption of concentrated feeds declined from the former 5 jin to 3.7 jin, and consumption of coarse fodder declined from the former 9 jin to 0.7 jin. From the time that shoats were weaned 45 days following birth until they were taken out of inventory at a weight of 130 jin after having been fed compound feed, their total consumption of concentrated feed was 436 jin, a 178 jin reduction from previous feed consumption. Extrapolating this figure to the whole prefecture means that had the 110,700 head of hogs removed from inventory (the 1980 figure) been fed with compound feed, more than 19.7 million jin of grain could have been saved, or if this amount of grain had been used to make compound feed, an additional more than 45,000 fat hogs could have been raised. A saving of more than 19 million jin of coarse fodder could also have fed more than 13,000 head of cattle, or more than 32,000 head of sheep and goats.

(2) Shortening of feeding time. In 1980, the prefecture raised somewhat more than 233,600 hogs, but removed only 110,700 head from inventory, an inventory removal rate of 47 percent. Each hog was fed for a period of about 2 years. Concentrated test feedings with compound feeds greatly shortened feeding time. Shangsanfenba Brigade in Zhongdong Commune, Jinta County, selected six stiff hogs that had been kept in inventory for 4 or 5 years for test feeding with compound feed over a period of 63 days, each hog averaging a daily weight increase of 1.1 jin and their individual weight increasing from 86 jin to 153.1 jin. At Zhongjie Third Brigade, four 67-day-old shoats were trial fed for 224 days. Their weight increased from 12 jin to more than 130 jin. Four 60-day-old shoats at the county fine breed hog farm showed weight increase from 20.5 jin to more than 130 jin after 135 days of trial feeding, and were removed from inventory within 6.5 months. Figuring a year from the birth of shoats until removal from inventory of fattened hogs fed on compound feeds, the ex-inventory rate for hog raising in the prefecture could be almost doubled.

(3) Lowering of feeding costs. During the trial period when 60 head of hogs were fed compound feeds at two test sites, weight gain amounted to 5,313.7 jin. Figuring a cost of 0.60 yuan per each jin live weight, output value was 3,169.46 yuan. Total feed consumption was 22,906 jin, at a cost of 0.12 yuan per jin, for a total cost investment of 2,429.22 yuan. Profits amounted to 740.24 yuan, or an average profit of 12.34 yuan, or 23.4 percent per head. Shoats weaned at 45 days and fed for removal from inventory upon reaching 130 jin consumed compound feed at an average of 436 jin per head. Figuring each jin at 0.12 yuan, costs amounted to 52.32 yuan per head. When fed with simple feed, consumption averaged 614 jin per head for costs totaling 73.68 yuan per head, or 21.36 yuan higher than the cost of feeding with compound feed.

Now the Jiuquan Prefecture units concerned are in the process of summarizing these experiences are are making appropriate material preparations. The prefecture has also trained 78 mainstay technicians, and are in the process of planning directed promotion throughout the prefecture as a whole.

'NANFANG RIBAO' DISCUSSES HAINAN AGRICULTURE

HK070943 Guangzhou NANFANG RIBAO in Chinese 2 Jun 82 p 2

[Article by Hou Xueyu [0186 1331 3558]: "Correctly Handle a Number of Relationship Problems in Building Great Agriculture on Hainan Island"]

[Text] Editor's note: Professor Hou Xueyu, member of the scientific council of the Chinese Academy of Sciences and a famous ecologist, wrote this article for this newspaper after he participated in the scientific comprehensive survey of the building of great agriculture and ecological balance on Hainan Island. Excerpts from that article will be published in this paper in over 2 days. [end editor's note]

Great agriculture includes plant production and animal production. Animals cannot produce food themselves. They live directly or indirectly on plants. Therefore, animal production constitutes the process of transforming plant products into such animal products as meat, eggs, milk, skin, hair and feathers. So great agriculture itself is a transformation process between matter and energy. To promote the ever-increasing biological production output and bring about a benign cycle in the natural world, it is necessary, in the light of certain ecological laws, to adopt scientific technical measures which are in conformity with science. That is, it is necessary to continually maintain the ecological balance between matter and energy exchange in the production process so that planting industries, forestry, economic forestry, animal husbandry and equatic product rearing can develop. Otherwise, disrupting ecological balance will invite a series of penalties from the natural world. For this reason, in order to build great agriculture, it is necessary to maintain an ecological balance in a regular and sustained way so as to ensure and increase the output of biological resources and their productive forces. This is the required basic point of view in accelerating the development of agriculture, forestry, animal husbandry, tropical crops and fishery on Hainan Island.

Below I would like to emphatically discuss my ideas on a number of problems in interrelationships in building great agriculture on Hainan Island.

1. Correctly Handle the Relationship Between Exploitation and Protection in Utilizing Biological Resources

In the natural rain forest and seasonal rain forest on Hainan Island, there is a lot of valuable timber, such as mu seng [2605 3932], zi jing [1311 0079], hua li [5363 2746], jiang xiang Tan [7100 7449 7806 2905], green plum, po lei [0980 1093], mesua ferrea, Hainan cephalotaxus drupacea, litchi and lujun pine. In the forests there are still many ornamental flowers and plants, such as orchidaceous plants and medicinal plants, chun sha ren [2504 3097 0088], yi zhi [4135 2535] and devilpepper as well as calamus rotan and white rattan which are used to weave rattan article furniture. After the destruction of forests, these shade-demanding and hygrophilous industrial plants are simply unable to grow. Birds, such as green pigeons, parrots, quails, partridges, gallus bankivas, crows and magpies, turtledoves, creasted mynas, woodpeckers and babblers, are numerous on Hainan Island. They all have the forest as their home. The felling of forest trees has made it difficult for birds to multiply and live and has resulted in a drastic decrease in the number of all kinds of tropical birds. At the same time, such activities as looking for food, mating, multiplying and living, of the tree-dwelling gibbons and macaque primates are all carried out in trees. Once the tropical rain forests disappear, these tree-dwelling mammals as well as moles and giant squirrels will find nowhere to live. As the saying goes: "When the tree falls, the monkeys scatter." Therefore, protecting the natural rain forest on Hainan Island means protecting the plant resources beneath the forest and the valuable animals and other reserves in the forest. Last November, I went to Australia to attend the 13th session of the international society of botany. Of the 13 proposals put forth by the assembly, 3 were proposals concerning the protection and study of tropical rain forest. China has only a meagre area of tropical rain forest which, is distributed on Hainan Island and Xishuangbanna [in Yannan] and this calls for special and good protection.

The mangroves on Hainan Island are also very valuable. In the mid 1950's, China still had 150,000 mu of mangroves, but now it has been reduced to only 20,000 or 30,000 mu. The mangroves are distributed on the mud beaches in the intertidal zone and exist both in rivers and streams. Fishes, shrimps and crabs dwell in these mangroves. The crowing cover of that part of the mangrove above ground is luxuriant and green while under the ground there are close and numerous prop roots, snakelike roots and hardened roots which crisscross and are twisted. This is conducive to keeping stormy waves in check and protecting the enclosed embankments. People call the mangrove the "natural bodybuard of the seacoast." Thus, protecting the mangroves means protecting fishery, agriculture and the diversified economy.

While surveying along the coast, and particularly in such places as Wanning, Wenchang and Qionghai, we say people carrying coral lime in trucks. It was to be used as building material. It was really a pity. Coral is where eucheuma grows and from the latter can be extracted agar-agar. Agar-agar is the raw material for making medical capsules and sugarcoating and agar-agar can also be used to cure high blood pressure and as a tonic. Sea cucumbers and fish also eat the algae living on coral. Burning coral to make lime means burning eucheuma, agar-agar, fish and sea cucumbers.

The above-mentioned natural forests in mountainous areas, mangroves along the seacoast and coastal coral are, on the one hand, themselves biological resources and also constitute the environment on which a series of animals and plants depend for existence. Therefore, we must not only rationally utilize but also protect them in a fairly good way. The argument claiming that protecting nature means "conservative thinking" and "naturalism" is obviously wrong. By protecting the natural biological resources, we mean protecting the capacity of resources to regenerate. Protection is a measure and utilization is the aim. Protection is aimed at better exploitation and utilization. Without protection, you can hardly talk about the permanent and continuous use of biological resources. We must not exploit the biological resources in a plundering way at the expense of long-term interests.

2. Correctly Handle the Intensive Farming and Extensive Cultivation in Increasing Grain Production

At present, although there are large areas of wasteland on Hainan Island, much wasteland and many barren hills are unsuited to developing grain crops because the soil fertility is poor; the gradient of the mountainous areas is great and water conservancy projects are underdeveloped. We must draw a lesson from the past experience in blindly expanding the area of farmland sown with grain crops. By exploiting mountainous areas with the slash-burn-and-abandon process, the per mu yield of "mountain products" was no more than 100 jin. The exploitation of mountainous areas with the slash-burn-and-abandon process resulted in the destruction of large areas of forests and serious soil erosion. Most of the flat tablelands are covered with sandy soil which is deficient in water and can hold neither water nor manure. Production output can hardly be ensured by planting grain crops on such soil.

Is it feasible to increase the number of multiple croppings? According to the present investigation of the five southern areas, the annual per mu yield of triple cropping of rice was only 500 jin, which was lower than that of double cropping of rice. The reasons for this state of affairs were mainly that the seasons were harsh and labor power was insufficient; the insect pest situation in midseason rice was serious; late rice precisely encountered the typhoon and low temperatures; the soil fertility was insufficient and so on. Proceeding from actual conditions, the most reliable way is still to carry out the cropping system of cultivating the land while farming it, that is to say, to practice the system of rotating and reversing paddy and nonirrigated-farmland industrial crops.

Take Chongpo commune of Ledong County for example. In 1980 the commune farmed 50,000 mu of early rice and total output was 13.1 million jin; in 1981, 4,500 mu of farmland was used to plant sugarcane and 500 mu for growing peanuts and fertilized water was concentrated on paddy fields. As a result, despite a reduction of 5,000 mu in the area sown with early rice, the total early rice output registered an additional increase of 2.15 million jin. In the very same year, the area sown with late rice was reduced by 5,000 mu but the total late rice output increased by 1.25 million jin. Some of the late-rice farmland was sown with peanuts. The total annual sums showed that the per mu yield of early and late rice increased from 764 jin to 1,022 jin; the increase in the total paddy output was 3.4 million jin and in addition, 17,000 tons of sugarcane and 320,000 tons of peanuts were reaped.

Why were there increases in both the per unit area yield and total output of paddy despite a reduction in the acreage of farmland sown with paddy? According to our analysis, first, in the past, peanuts and sugarcane were driven to hillslopes thus resulting in low yield. The production did not even cover costs. Now substituting peanuts and sugarcane in paddy fields has improved the production conditions and regulated the labor force. Each mu of sugarcane only needs 25 laborers while each mu of two-crop paddy needs 50 laborers. Sugarcane can be planted before the transplanting of early rice seedlings and thus the freed labor force can be concentrated on winding up the sowing of early rice before and after the beginning of spring. Thus we can keep clear of the outbreak period of yellow rice borers on the one hand and on the other finish harvesting early rice before the rainy season comes so as to prevent early rice from going mouldy and rotten. Second, spring drought on Hainan Island is relatively serious. After some of the paddy fields were planted with sugarcane and peanuts, the use of water was economized and thus the conserved water could be concentrated on early rice. Third, rotating paddy and dry-land crops helped regulate the paddy field soil conditions, such as moisture, fertilizer, air and heat, made the soil become aerated and prevented the emergence of reducing materials which are harmful to paddy roots. Peanut root-nodule bacteria can, in addition, fix and turn free nitrogen in the air into nitrogen fertilizer and peanut roots can be left in the fields as manure.

Another key problem in increasing grain production is Hainan Island is neutralizing its soil acidity. Apart from a small number of areas, most of the areas of the whole island have strongly acidic soils. This is detrimental to the growth of grain crops. It is advisable to neutralize the soil acidity by applying more limestone powder to the soil. This not only can provide the soil with nutrients, such as calcium and magnesium, increase the effectiveness of existing nutrients, improve the soil structure and increase the air permeability of the soil but can also slowly dissolve the manganese and aluminum poisons existing in acid soils, and particularly can be conducive to the multiplication of nitrifying bacteria and symbiotic and nonsymbiotic azotobacteria. Limestone can be found within the boundaries of Dan, Yan and Ledong counties. We can grind limestone to powder and directly apply limestone powder to farmland. It is not necessary to burn limestone into lime.

Besides, the improvements in water conservancy and in product varieties, we must not neglect the mixed application of nitrogen, phosphorits and potassium fertilizers and organic fertilizers or green manure and the prevention and control of plant diseases and elimination of pests.

3. Correctly Handle the Relationship Between Rubber and Other Tropical Crops in Developing Tropical Crops

Hainan Island has more than 70 years of history in introducing and cultivating fine varieties of rubber. Before liberation, China had no more than 40,000 mu of rubber with the annual dry rubber output being 600 tons. After liberation, rubber production was developed on a large scale. At present Hainan Island already has over 4.3 million mu of rubber plantation with the annual dry rubber output being 70,000 tons. All this is a significantly great contribution to the country.

At present, one important way to increase rubber output is to increase the per area unit yield on the basis of the existing acreage under cultivation. In this respect, the South China Tropical Crops College and the South China Research Institute have achieved a series of research findings. They adopted such measures as the terracing of mountain slopes, plant covering, [word indistinct] improving, application of fertilizers, the building of forest networks and the turning of seedling plants into budding plants. So long as the popularization of these measures are upheld, it is entirely possible to increase the present per mu yield of 50 kilograms of dry rubber of the state farms to over 100 kilograms. The natural environment of Dan County where the college and research institute are located belongs to a region which frequently suffers from "moderate gales and light cold currents." Their experimental plots have produced more than 200 kilograms per mu. If the farms in the southern areas of the island which have relatively favorable climatic conditions try hard to reach half of the output of the experimental findings of the "college and research institute," that is, the level of 100 kilograms per mu, this will mean that these farms have increased their production by 100 percent. This is the equivalent of expanding the acreage under cultivation by 100 percent.

While increasing the per area unit yield of rubber, an important strategic principle for bringing the strong points of Hainan Island into play is to develop, in the light of the natural characteristics of the various localities, other tropical crops in a planned way in the regions which are unsuitable for planting rubber. Coconuts are a traditional crop of Hainan Island. Cocunuts have many uses and every part of the coconut is useful. They can adjust to various kinds of soils. They can grow very well in the seashore saline soil which are not suited to growing other crops. Furthermore, an ordinary force 3 or 4 wind will not affect its growth, development of bearing of fruit and its output will not be greatly affected by a force 7 or 8 wind. Coconuts can be developed along the coast of the whole island. The areas with low elevation along the coast within Nansi County are the most suitable places for developing coconut production.

Betel has not always been one of the important cultivated crude drugs from South China. The masses in the various southern counties [word indistinct] betel nut as a habit. At present our country has to import 50,000 dan of betel nut from southeast Asian countries every year. In order to meet domestic demands, developing betel nut production in a planned way in the mountain valleys and gullies, on the riverbanks and lands scattered around the fields of the central mountainous areas with an elevation under 300 meters should be a task not to be ignored for Hainan Island.

Hainan Island has a history of 50 years in planting cashews, which is one of the world-famous dry fruits. Their growth is restricted by temperature factors in a most rigid way but they are resistant to aridity and wind. On the other hand, too much rain will be harmful to its blooming and its bearing of fruit. As far as the other crops are concerned, the soil fertility of the sandy soil along the southern seashore is insufficient. However, cashews can normally grow and bear frult there. Therefore, cashews do not vie with other tropical crops for land. Cashew production can be vigorously popularized in the tableland in the southeastern areas of the island where the dry season is obvious, sunlight is abundant, warmth is rich and the typhoons are relatively rare.

Temperature does not constitute a restricting factor for the planting of robusta coffee in Hainan island. The growth of robusta coffee needs a shady and wet habitat in which rainfall is fairly well-distributed. Robusta coffee can be popularized in the eastern areas where shady forest trees grow thickly. Pepper has great economic value. Generally speaking, the per mu output value of pepper is 2,000 to 3,000 yuan. It needs calm and tranquil surroundings. So it is relatively suitable to cultivate pepper within the eastern and southern shelter forest network where rainfall is relatively abundant. In the early 1960's, oil palm was substantially developed in Hainan Island but generally speaking it resulted in failure. However, in 1975 the Tenera variety was introduced from abroad and the 1979 per mu yield of oil palm was 230 kilograms. Tenera is expected to be developed in southern areas of the island as the "king of oils." Yet more time is needed for further experiment before it is popularized. Large-leaved tea was introduced here from Yunnan Province in the 1960's. It is mainly distributed in the southeast and central-south farms which are not suited to planting rubber. When planting tea, some farms use rubber trees as shade trees. It is better to replace rubber trees with leguminous Taiwan acacia. The reasons for this are that 1. Taiwan acacia is so strongly wind-resistant that it cannot be broken by a typhoon; 2. The root tubers of leguminous plants can fix nitrogen; 3. Grown together, rubber and tea may possibly vie with each other for fertilizers; and 4. Rubber trees on Hainan Island have powdery mildew which need to be treated with farm chemicals which can easily bring pesticide pollution to tea trees and affect export quality. Sugarcane is one of the most economically valuable crops and grows on Hainan Island all the year round. But at present its per area unit yield is too low and there is still enormous potential for increasing its output.

Hainan Island must devote herculean efforts to encourage the development of traditional tropical fruits, such as pineapples, litchis, bananas, longans and mangoes. In the eastern hilly areas with arid red soil, it is advisable to establish a production and processing base which gives priority to pineapples. It is also advisable to intercrop pineapples in rubber, coconut and betel palm plantations so as to utilize the weaknesses to foster the strong points. Hainan Island is one of the original homes of litchis. Qiongshan County, in particular, has always been a major litchi producing area. Great efforts should be exerted to revive litchi production there. Bananas on Hainan Island can, in winter, still grow and bear fruit as usual. Apart from bananas which can be separately cultivated in places close to the villages and the "five-sides" land which have relatively favorable water resources, it is also foreseen that bananas and paddy can be rotated. Hainan Island must become a national banana exporting base. Hainan Island is one of the major mango producing areas. Mangoes can grow very well in the sandy land along the coast of the southwestern areas of the island where rainfall is scarce and the winter-spring dry season is fairly long. Hainan Island has natural conditions very favorable for growing watermelons in winter. It is also close to Hong Kong and Macao and is in a position to export watermelons in the off seasons and thus earn more foreign currency.

CSO: 4007/433

BRIEFS

FLOODING IN SHANTOU PREFECTURE--Heavy rain fell in Shantou Prefecture from 28 May to 2 June. Huilai, Haifeng and Lufeng counties which are in the western coastal area have received more than 400 mm of rainfall, and Haifeng in particular received 520 mm. In other counties, some 100 to 200 mm of rainfall were recorded. Throughout the prefecture, some 400,000 mu of fields were flooded. In Huilai County where the losses caused by the disaster were serious, more than 24,000 people in 19 villages were stranded by the floodwaters, 219 houses collapsed and some 90,000 mu of ricefields were flooded. After the disaster, the Shantou Prefectural CCP Committee and the county CCP committees of the flooded areas immediately sent work teams to help settle the masses in the disaster-stricken areas, help them drain waterlogged areas, salvage flooded crops, and repair fences and breaches. [Text] [HK040645 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 3 Jun 82]

BEAN CROPS HARVEST--Guangdong Province has reaped a bumper harvest of bean crops in this year's spring harvest. According to the statistics of departments concerned, this year's wheat harvest increased by 9.9 percent, the harvest of dry-land crops increased by 6 percent, and the bean harvest increased by 20 percent. In Shantou Prefecture, some 840,000 mu of wheat was cultivated last year, showing an increase of 160,000 mu over that of the preceding year. Due to improvement of management and the fact that fine seed strains have been used, the average production per mu amounted to 255 jin and the total output increased by 32 percent. In Zhanjiang Prefecture, some 280,000 mu of beans were grown last year, showing an increase of 60,000 mu over that of the preceding year. The total harvest was 32 million jin, showing an increase of 18 percent over that of the preceding year. [Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 16 May 82 HK]

TRICHOGRAMMA RESEARCH--Guangzhou, Jun (no day) (XINHUA)--China's achievements in using trichogramma research to eliminate other agricultural parasites won attention at the first international symposium on this subject in France, said Li Liying, vice president of the Institute of Entomology under the Guangdong Academy of Sciences, who has recently returned from the symposium. China is one of the countries which have the greatest trichogramma-using areas in the world. Since the early 1950s, it has been using trichogramma to kill the sugarcane borer, pine caterpillar, corn borer, cotton bollworm and rice grassleaf roller and has built a network for the popularization of the science. Li Liying said China has reached the world advanced level in Trichogramma culture in vitro and China's achievements in trichogramma classification, physiology and ecology were praised at the symposium. Li Liying was elected a council member of the International Committee of Trichogramma Research at the meeting at which she and Gao Yiguang, another participant from the biology department of Wuhan University reported on trichogramma research and utilization and its culture in vitro in China. The meeting also proposed that the second international symposium be held in China in 1986. [Text] [OW070750 Beijing XINHUA in English 0728 GMT 7 Jun 82]

BRIEFS

RICE CIRCULAR--Guangxi Regional People's Government issued a circular on 12 May on making early and good arrangements for late-rice production. The circular said: Stabilizing the sown area of late rice is an important condition for increasing production. After making readjustments over the past years, the sown area of late rice was reduced to 1,955 mu last year, showing a decrease of 10.5 percent over that of 1977. Besides stabilizing the cultivated area, it is also necessary to pay attention to nursing young plants and promoting sowing techniques. In conclusion, the circular said: In order to seriously implement the various policies, all areas must strengthen leadership over agricultural production and farming techniques. PEASANTS URGED TO GROW COTTON DESPITE DROUGHT CONDITIONS

Bumper Harvest Planned

Shijiazhuang HEBEI RIBAO in Chinese 15 Apr 82 p 1

[Article: "Triumph Over Serious Drought for Timely Completion of Cotton Planting Tasks"]

[Text] This is a year for further readjustment of the national economy. Hebei Province has diligently put into effect a program of "positively no slackening in grain production while actively developing economic diversification," and "taking the planned economy as primary, and regulation by market mechanism as secondary to continue to readjust agricultural crop patterns." While maintaining the grain acreage virtually stable and assuring increases in grain output, an expansion in the province's cotton growing area to 11 million mu has been planned for a total output of 6.07 million dan of ginned cotton. This possesses extremely important strategic significance for making the most of the province's natural economic advantages, for increasing peasant income and national wealth, and for enlivening the agricultural economy as well as the entire national economy. All jurisdictions are to assure quality and quantity in accordance with planting plans handed down by the state, and they should not delay fulfillment of planting tasks in order to lay a foundation for winning a bumper cotton harvest this year.

A conspicuous problem confronting us in completion of this year's cotton planting tasks is the serious drought. Statistics from all prefectures show that only 5.75 million of the 11 million mu cottonfield area can be watered or maintain watering. For most of the remainder in will be necessary to combat drought by dibbling in seeds. Consequently, it is necessary to make combat against drought a key link in planting cotton. All jurisdictions should devote further attention to doing a good job of maintaining irrigation facilities and equipping pump wells, fully tap the potential of existing water conservancy facilities, use water in a planned way, conserve use of water, strive to enlarge the cottonfield area that can be irrigated, and use every available means to plant on time, and to assure a full stand of seedlings after planting.

A good job of combat against drought to plant cotton requires the further bringing into play of production responsibility systems and arousal of the enthusiasm of the brad masses of cotton growing peasants. Those who have not yet signed contract agreements should devote strict attention to signing them. The signing of contract agreements should place under centralized control all large farm machines and implements, major water conservancy facilities and crucial planting techniques and measures that should be placed under centralized control, and contract all that should be contracted so that cotton growing peasants can devote themselves to fighting the drought and planting free from anxiety. Right now it is particularly important that responsibility systems be put in place for pump wells in order to make fullest use of the role of pump wells in fighting drought and planting. Those households that have difficulties in combating drought and planting following the practice of a responsibility system of "double contracting" [a system of fixing output quotas based on households and a system of peasant households assuming full responsibility for task completion], should be helped by production teams so that they plant sufficiently and well the cottonfields for which they have contracted.

Simultaneously with the fight against drought it is also necessary to strengthen technical guidance. Most of this year's increase in cottonfields in the province has been in Heilonggang Prefecture, where quite a few communes and brigades lack skills in growing cotton. This situation requires all the more that leadership organizations at all levels enlarge the number of agricultural technicians, go down into grassroots communes and brigades, and launch more extensive technical guidance and technical instruction work. For the province as a whole, the following several points should be given prominence in providing technical guidance for planting: First is the need for diligent summary of experiences and adaptation of general methods to local situations in setting the time for planting so that it is neither too early nor too late, so that work is begun early, so that quick action is taken at the right time, and so that vigorous efforts are made to get "seedlings in April." Second, a considerable portion of the large quantity of cotton varieties introduced from outisde the province this year contain seeds with diseases, so all jurisdictions should diligently perform seed selection, sun the seeds, and treat them chemically. Third, this year's area for combat against drought and planting is large, and once planting is done, it will have to be tended at once, every row and every field being inspected. Where soil moisture conditions are good, compacting of the soil should be done to increase soil moisture. Where soil moisture is low or poor, timely action should be taken to enhance soil moisture, to promote early sprouting from the soil of cotton seedlings and full stands of cotton.

CCP committees and governments at all levels in cotton growing regions should make the fight against drought to complete cotton planting their main current task, and give diligent attention to doing it well. All old hands and less experienced hands in major cotton growing counties and communes should personally take charge. Leaders at all levels should lead large numbers of cadres into the front lines of cotton production for practical study and solution to real difficulties existing in the combat against drought to plant cotton. Where problems exist for grassroots leadership teams, energetic cadres must be dispateched at once to help solve them, and to genuinely energize the broad masses of grassroots cadres and masses of commune members.

Cotton offices at all levels should do organization and coordination work under the direct leadership of CCP committees and governments and make the most of the functional role of units concerned, to do a genuinely good job of supplying diesel oil, machine oil, rural electricity, chemical fertilizer, and pesticides, and release of down payment funds toward the purchase of cotton to assure smooth performance of the task of fighting drought to plant cotton.

Pointers Given on Planting

Shijiazhuang HEBEI RIBAO in Chinese 15 Apr 82 p 1

[Article: "Concentrate Forces To Triumph Over Hardships for Timely and Sufficient Cotton Planting"]

[Text] The time for cotton planting is now at hand. In order to assure both quantity and quality and fulfill the province's 11 million mu cotton sowing task on time, comrades in charge at the Provincial Cotton Office recently made the following remarks to the correspondent.

Preparations for sowing have been very good. Ninety-six percent of the province's cotton growing production teams have set up various forms of responsibility systems linking remuneration to output, and among the broad masses of cotton growing peasants desire to grow cotton is very high. The 11 million mu cotton growing task assigned the province by the state has been applied to specific fields, for most of which contracts have been signed. Preparations for the planting of cottonfields centering on the fight against drought got underway earlier than in previous years and were done more quickly. Four million mu have already been irrigated. Sufficient quantities of seeds have been made ready, and supplies of crude fertilizer, phosphate fertilizer, pesticides, and superior varieties are greater than in previous years. Additionally, training has been given all levels of leadership cadres and technicians numbering more than 2.5 million people. All this has been done by way of laying down a material foundation for prompt planting. However, this year's drought situation is particularly serious and water resources are extremely inadequate. There are numerous new cotton growing areas and planting tasks are great. Numerous cotton varieties have been introduced, so possibilities for transmitting diseases are extremely great. In addition, the work of preparing for planting has not been done evenly, and many difficulties still exist in planting. Consequently if cotton sowing tasks are to be completed so as to assure both quality and quantity, it will be necessary to make arduous efforts. Currently the following several points should be given diligent attention.

1. Use of every available means to combat drought for planting. Almost half of the dryland cottonfields in the province are dry all the way down to the plow pan, and moisture content of soil in the cultivated layer of cottonfields is 6 to 7 percent, while soil moisture requirements for sprouting and cotton seedling growth are above 14 percent. Very clearly, unless the moisture of an overwhelming majority of cottonfields is increased it will not be possible to plant them. Therefore, perseverance in resistance to drought must be

central in this year's cotton planting. Pump well maintenance must be quickly taken in hand and wells should be fully equipped so as to be able fully to tap existing water conservancy facilities, using every available means to enlarge the area that can be irrigated to provide soil moisture. Where water resources do not suffice, the method of digging high yield ditches and high yield pits has to be adopted, water pooled for use, and water use conserved. Places lacking water conservancy must devote strenuous efforts to the hauling by water on vehicles and on poles carried by people, and to combat drought by dibbling seeds. Experiences in digging large pits, irrigating sufficiently and putting numerous plants in a single hole should be promoted to assure full stands and density. In addition, special emphasis should go to conservation of moisture, to reducing moisture evaporation insofar as possible, and to achieving genuinely sufficient soil moisture for planting. On carefully leveled soil where soil moisture conditions permit, machine sowing of cottonfields should be promoted. When seeds are sown with a hand drill, a large hoe should be used to compact the soil after planting to preserve soil moisture. When soil moisture conditions are not good or where water is carried on poles for the dibbling of seeds, general methods should be adapted to local situations in the use of enclosing [0545 0545] after sowing, planting with water and enclosing, or planting in mounds. The drier the soil, the greater the need to assure planting quality, guarding against planting too deeply and smothering the seeds, or too shallowly causing them to dry out.

2. Diligent seed treatment. Emphasis should be placed on grain by grain selection of seeds, and seeds should be sunned continuously for 34 hours to increase the germination rate and to disinfect them. Before sowing, germination rate testing should be done, and the seeds should be soaked in chemicals. When seeds are planted fairly early, it is not necessary to hasten germination, but when planted fairly late, the seeds should be made to germinate slightly before planting. Particularly noteworthy is the extremely great possibility that the large quantities of Lumina No 1 cotton seeds brought in from Shandong may contain fusarium yellows disease germs. All jurisdictions should arouse a high degree of serious attention to this problem, and disinfecting should be done by either production teams or production brigades. Plant protection technique units at all levels must do a good job of teaching and giving guidance in quarantine and seed treatment techniques. In order to prevent and control diseases and insect pests, great efforts should be made to promote the soaking and mixing of seeds for sulfate delinting, and in 402, carbendaxol, furadantin, and 3911 pesticides to assure the cotton's safe growth.

3. Timely planting. Experience has shown that the best time for planting cotton in Hebei Province is during the last 10 days of April. A folk saying goes, "Around the time of the grain rains (20 April), plant cotton and beans." In general, when the soil to a depth of 5 centimeters remains at above 14 degrees, or when saline-alkaline soil remains at above 16 degrees, a concerted effort should be made to plant. In the major cotton growing areas of the south central part of the province, efforts should be made to finish sowing of cotton by the end of April. In the north, in seriously saline and alkaline cottonfields, and where combat against drought must be done, cotton

planting should also be finished by early May. In order to assure a full stand of cotton, care should be taken to grow some reserve seedlings for transplanting to spaces where seedlings do not come up. Some seeds should also be made ready for use in growing seedlings that are lacking. In addition, all jurisdictions should adapt general methods to local situations to use the new plastic mulch and seedling transplanting techniques.

4. Seed fields should be planted in sufficient quantities and well to produce seeds for next year's cotton production. All jurisdictions should set aside a seed field acreage to meet next year's cotton planting needs, and select fine variety seeds. Seed corps, specialized seed growing people or seed growing households should be designated and contracts signed for assured outputs and for a good job in sowing and tending sown fields. Disease free land should be selected for seed fields; fine varieties should be selected; and production and management conditions should be superior.

5. A good job of technical guidance. Agricultural technicians at all levels should go into the front lines of cotton production, devote attention to work in all areas by drawing upon experiences gained in key points, and disseminate planting techniques to the myriad households. At the same time, systems of responsibility linked to output for technical cadres should be perfected with all possible speed, and the role of 1,000 mu cotton growing brigades and 10,000 mu cotton growing commune demonstration sites brought into full play.

6. Leadership of cotton growing should be strengthened. Leaders at all levels in cotton growing areas should plant cotton on time in sufficient amounts and well, and devote strict attention to this as a key task in current agricultural production. Cadres at all levels should use the method of level by level dividing up of assignments, and put into effect systems of personal responsibility for leadership cadres. They should go down to the grassroots to investigate and study to solve real problems, to promote advanced experiences, to devote strict attention to the implementation of measures, to promote work in all areas by drawing on experiences in key points, and to promote cotton planting work. Technical units are to be organized to work on technical difficulties that arise in cotton planting. Supply and marketing, farm machinery, water and electricity, finance and trade departments concerned should actively coordinate and energetically help each other to do a good job of material supply, of pooling the wisdom and efforts of everyone, and in victoriously completing the task of fighting drought to plant cotton.

AGRICULTURAL DEVELOPMENT SEMINAR--The Henan Provincial Agricultural Society, Water Conservation Society, Forestry Society and 14 other academic organizations held a seminar on speeding up agricultural development in Henan from 17 to 22 May. Some 198 people attended the seminar and 178 theses were submitted to the seminar. The seminar mainly discussed ecological improvement, exploitation and utilization of natural resources, comprehensive development of agriculture, forestry, animal husbandry, sideline production and fishery and other major issues. Han Jiangcao, secretary of the provincial CCP committee and vice governor; Cui Guanghua, vice governor; (Luo Gan), vice chairman of the Standing Committee of the provincial people's congress attended the seminar and gave speeches. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 25 May 82 HK]

WATER POLLUTION--A water supply project for 20,000 people has gone into operation in (Xiaoyu) commune in Gong County in recenty days. The peasants said: "The serious water pollution has been completely solved, thanks to the direct concern of chairman Hu Yaobang and party and government leaders at all levels." In recent years some 30 factories producing items such as chemicals, metals and paper have started operations in the vicinity of this commune, seriously polluting underground water. This situation was reported to the departments concerned, but was never solved. "Later, peasant representatives of the commune wrote a joint letter to Comrade Hu Yaobang. On receiving this letter, Comrade Hu Yaobang immediately issued an instruction ordering the principal responsible comrades of the Henan Provincial CCP Committee to deal with the matter personally. The leading comrades of the provincial party and government attached great importance to this. Vice Governor Yue Xiaoxia and general office secretary-general (Guo Tan) personally set to work to solve the problem. Provincial economics committee director (Li Ying) received representatives of the commune. (Li Qiaoting) and (Wang Tianzhao), leading comrades of the provincial environmental protection office, went to observe the pollution on four occasions." After consultations with all parties, the factories responsible for the pollution paid 800,000 yuan in compensation to build a water supply project for the peasants. The local factories also provided the equipment for the project. [HK070534 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 6 Jun 82]

AUTUMN GRAIN MEETING--On 3 and 4 June, the Henan Provincial Agriculture Department held an urgent meeting in Zhengzhou on the production of autumn grain. The meeting analyzed the situation of the production of autumn grain in the province, implemented the tasks of the production of autumn grain and worked out measures to strive for a bumper autumn harvest. The meeting called on people in the province to do well in the production of autumn grain. All places must eliminate the idea of attachimg more importance to summer grain and less to autumn grain. In accordance with the principle of the CCP Central Committee on not relaxing the grasping of grain production and on actively carrying out diversification, all places must strive to increase the production of autumn grain. ENTERPRISES READJUSTED--The Hubei Provincial People's Government recently approved the report of the provincial people's commune enterprise administrative bureau on readjusting the commune and brigade enterprises. The report of the provincial people's commune enterprise administrative bureau pointed out: The province's commune and brigade enterprises have been developing fast since the 3d Plenary Session of the 11th CCP Central Committee. However, management is still poor and production costs are still too high in some commune and brigade enterprises. Therefore, it is necessary to readjust the commune and brigade enterprises. The crux is to readjust the financial system, perfect the economic responsiblity system and improve the economic returns. The Hubei Provincial People's Government has urged people's governments at all levels to include this task in their daily agenda and do a good job of grasping it. FORESTRY CONFERENCE HELD--The Hunan Provincial CCP Committee and the provincial government recently held a conference on forestry to look into the issue of how to fully exploit and utilize the mountainous land. The conference demanded that all places do well from start to finish in fixing rights of forests, fixing private forests and fixing the forestry production responsibility system, resolutely prohibit indiscriminate lumbering and protect the existing forests. Attending were responsible comrades of the provincial CCP committee, the provincial government and the provincial people's congress Standing Committee, including Wan Da, Sun Guozhi, Wang Zhiguo, Dong Zhiwen, Zhang Wenguang and Qi Shouliang; responsible comrades of all prefectures and municipalities who are in charge of forestry; and forestry bureau directors. Zhang Pinghua also attended and spoke. The conference stressed that fixing rights of forests, fixing private forests and fixing the forestry production responsibility system are a fundamental measure for developing forestry. At present, more than half the production teams throughout the province have completed this work. Around the season for crash-reaping and crash-sowing, all places must concentrate their forces on this work to ensure the completion of this work before reaping late rice. JIANGSU STATE FARMS SET SOME ALL TIME HIGH RECORDS

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 1, 1982 p 4

[Article by Propaganda Department, Jiangsu Provincial State Farm and Land Reclamation Bureau: "Every Farm and Plant in the Jiangsu Provincial State Farm and Land Reclamation System Increases Output and Profits by Relying on Policies and Science To Pick Up Speed in the Midst of Readjustment"]

[Text] In 1981 the Jiangsu State Farm and Land Reclamation System surmounted natural disasters including spring drought, autumn floods, typhoons, and rainy, overcast weather to win an all-around bumper agricultural harvest, and continued growth of industrial production. Despite a 400,000 mu reduction in the grain growing area, output totaled 400.42 million jin to exceed the bumper harvest of 1980. Ginned cotton output totaled 310,000 dan, a 40 percent increase over the previous year; and profits amounted to 60 million yuan for a net surplus of 45 million yuan, a 30 percent increase over the previous year. Total grain and cotton output, gross output value of industry and agriculture, and economic profits exceeded the all time highs. Each of the sytem's 32 farms and forests, and industrial transportation enterprises belonging to 14 bureaus, showed profits for an "all around victory" for the bureau as a whole. This was also an all time first for the Jiangsu State Farm and Land Reclamation System.

Last year the Jiangsu State Farm and Land Reclamation System continued to carry out a program of readjustment in which it guaranteed fulfillment and overfulfillment of grain production plans while at the same time expanding by 60,000 mu the growing of cotton and other economic crops, and actively developed economic diversification. Output value from farm operated industries and economic diversification increased by more than 20 percent over the previous year, and accounted for 60 percent of farm gross output value for an initial change in the unitary economic structure of state owned farms. In the midst of readjustment, industrial development speed reached 19 percent, and the light and textile industries accounted for 90 percent of total industrial output value. In 1981 business profits increased 46 percent over the previous year.

More than 98 percent of the company-size farming, forestry, livestock raising, and sideline occupation units in the Jiangsu State Farm and Land Reclamation

System adapted general methods to local situations to put into effect various forms of a system of production responsibility including those linking remuneration to output, and specialized contracting, with rather equitable handling of economic benefits for the state, enterprises, and individuals. They vigorously launched scientific farming, established and perfected farm science organizations at various levels, actively promoted various techniques for increasing yields, equitably arranged crop patterns, linked nurture and use of the soil, did rotational cropping, and purged alkalinity from the soil to improve it. They conducted a soil survey throughout the system's 1.13 million mu of cultivated land and its 200,000 mu of wasteland to provide accurate and reliable data for scientific farming. Taking account of different soil conditions, 410,000 mu was planted to green manure during the winter and summer of 1981; stalks and stems were returned to field on 450,000 mu, and more than 10,000 tons of phosphate fertilizer was used. Fine varieties of major crops such as wheat, barley, naked barley, paddy rice, cotton, and soybeans were put into use, and chemical herbicides and aerial spraying to control pests was done on areas totaling 550,000 mu and 500,000 mu respectively. Throughout the system, overall mechanization for crops of all kinds reached more than 70 percent, including a 94.4 percent mechanization of wheat, barley and naked barley production. This gave vigorous impetus to development of scientific farming and greatly increased labor productivity rates.

GENERAL UPWARD TREND IN OUTPUTS REPORTED

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 1, 1982 p 4

[Article: "Last Year Nei Monggol's Agricultural and Livestock Farms Had Good Yields"]

[Text] In 1981, the Nei Monggol Autonomous Region's agricultural and livestock farms brought in fairly good yields. A comparison of 1981 with the year before shows a 9.8 percent increase in grain output, a 5.9 percent increase in commodity grain, a 76.5 percent increase in edible oil output, a 4.5 percent increase in the rate of livestock increase, an 18.9 percent increase in milk output, a 5.3 percent increase in gross output value of industry and agriculture, and a 30 percent decline in net loss figures.

Reasons for the fairly good yields from Nei Monggol's agricultural and livestock farms were, first, further implementation of the party's economic policies, institution of production responsibility systems for gradual change in the situation of eating out of a "large common pot," and rather high enthusiasm on the part of the mass of staff and workers. Second was an increased level of scientific farming and scientific livestock raising. All units devoted attention to key measures of major significance for increasing yields and increasing earnings in their own area and in their own units. Most of the major farm crops on farms belonging to the Hailaer Farm Administration, for example, were sown during the period for high yields, and comprehensive measures were taken to eliminate weeds to reduce damage to the harvest, which produced a good harvest. Some agricultural and livestock farms also increased capital construction of grasslands and devoted efforts to livestock propagation and survival, thereby increasing the total rate of livestock increase. Third was continued surmounting of the single kind of farming, single kind of planting, and single kind of livestock raising mentality, with some measures being taken to develop economic diversification and to widen sources of wealth, which also won some preliminary success.

BRIEFS

OIL-BEARING CROPS--Sowing of oil-bearing crops has been completed in Nei Monggol Autonomous Region. The region cultivated 7.69 million mu of oil-bearing crops, an increase of 450,000 mu--6.2 percent--over 1981. [SK052209 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 4 Jun 82 SK]

NEWBORN ANIMALS--Abag Banner and Linhe County, Nei Monggol Autonomous Region, have scored remarkable achievements in delivering and protecting newborn animals. According to statistics compiled on 20 May, the banner has over 145,000 head of newborn livestocks born by its some 144,000 head of female animals. The county scored a 23,000 increase in newborn livestock over the 1981 figure. The county's survival rate of newborn animals is 96 percent. It has 100,000 head of newborn livestocks. [SK070635 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 5 Jun 82 SK]

REGION'S WHEATFIELDS--Field management is in full swing in Nei Monggol Region. This year the region sowed 13 million mu of wheat, and all of them have come up out of the ground. Over 80 percent of wheat seedlings are second grade. The region is making preparations for wheatfield management. By the end of May, 8.13 million mu of wheatfields were hoed, 4.61 million mu were irrigated and 2.85 million mu were applied with chemical fertilizer. [SK070624 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 6 Jun 82 SK]

MARSH GAS PITS--In the past few years, Nei Monggol Region has constructed over 5,000 marsh gas pits. This year the regional agricultural commission has appropriated 450,000 yuan of special funds to develop the following projects: 1) Support Xingan, Jirem, Ju Ud, Ulanqab and Ih Ju Leagues to build 3,000 marsh-gas generating pits. 2) Sponsor a regional marsh gas training class in Aohan Banner. 3) Build on trial basis a new energy resources village in a brigade in Helin County. SHAANXI

LOESSLAND WATER, SOIL CONSERVATION FARMING TECHNIQUES OUTLINED

Xi'an SHAANXI RIBAO in Chinese 16 Mar 82 p 2

[Article: "Water and Soil Conservation Farming Method. Little Investment, Quick Results, Great Increases in Yields and Easily Spread. Shaanxi Province Water Conservation Technicians Propose Adaptation of General Methods to Specific Situations for General Spread Throughout Loess Highlands"]

> [Text] Editor's Note: This proposal from Comrades Guo and Zhang has great economic value and merits the serious attention of leaders at all levels in all places, particularly in the loess highland region. In addition, their spirit of initiative in fulfilling responsibility as "staff officers" for the four modernizations, and providing views as a "brain trust" merit even greater recommendation.

Recently two technicians at the Provincial Water and Soil Conservation Bureau, Guo Zhixian [6753 1807 6343] and Zhang Liming [1728 0448 6900], wrote an article proposing the adaptation of general methods to specific situations in the loess highlands for the promotion of water and soil conservation farming methods.

In the article they said that the strip fields and the trough fields in the area north of the Wei, the furrow and ridge, and horizontal furrow farming as well as intercropping, rotation of grass and field crops, and planting of swaths of grass between fields in northern Shaanxi were all a part of water and soil conservation farming methods (also called water and soil conservation farming measures). Their main advantages are: ability to reduce soil erosion, helping to conserve soil and water. Water and soil conservation farming methods can transform the minor features of slope faces and increase the slope face's roughness so that water and soil are retained in place. Horizontal ditches in mountain areas are really contour farming, the ditches and ridges intercepting runoff and reducing erosion, conserving soil, water and fertility. Experiments conducted by the Shuide and other water conservation stations under the Huang He Water Conservancy Commission show that when the slope is as small as under 20 degrees, in a situation of ordinary downpours runoff from horizontally ridged mountainlands is about 80 percent less than from smooth cultivated land, and erosion is about 90 percent less. Once a native slope has been changed into an area of ridged fields, surface water and soil erosion can be reduced by 84 to 99 percent and runoff reduced by 70 to

98 percent. In the Huang He basin of Shaanxi Province, cultivated land on slopes amounts to 35 million mu with a population of somewhat more than 16 million. Figuring on the basis of the situation in Zichang, Ganquan and Ansai counties in northern Shaanxi, where one person farms 1 mu, this region could be expanded to 16 million mu. Estimating a benefit of 10 cubic meters of runoff retention and the holding back of 4 tons of silt per mu per year, runoff would be anually reduced by 160 million cubic meters, and erosion would be reduced by 64 million tons, which is 8 percent of the amount of silt dumped into the Huang He by Shaanxi Province. Second, when water and soil conservation farming methods are used, planting can be done and benefits derived in the same year as the work is done. A look at experiments performed in some areas shows that after ridging of fields has been done on slope faces with an angle of less than 20 degrees, corn yields increased by an average of 16 to 20 percent, gaoliang yields increased by an average of 10 percent or so, and potato yields increased by an average of about 18 percent. According to a survey done at 22 production teams in 11 communes in the hill ravine area of northern Shaanxi, use of the Chuanyuan ridge and ditch planting method produced corn yield increases of more than 220 jin per mu as compared with the old planting method, i.e., a yield increase of 64 percent. Mountainland horizontal furrow planting of millet increased yields by 153 jin per mu, i.e., a yield increase of 1.4 times. Potato yields increased by 760 jin per mu, i.e., a yield increase of 80.5 percent. For other crops, including wheat, soybeans and broom corn millet, yield increases ranged from 50 to 100 jin per mu. If each person in northern Shaanxi were able to plant 1 mu and each mu produced an increased yield of 50 jin, the total increase in output would be 180 million jin. Third, the water and soil conservation farming method can save on investment and is suited to extension over wide areas. It is through the use of "indigenous" methods that the water and soil conservation farming method scores. It does not require large amounts of investment nor does it require concentration of large workforces or the use of specially manufactured farm implements. Places having the conditions can do machine farming or they can use animal power. Even in fairly distant mountain regions where work teams are small or in places practicing the linking of output to individual households or fixing output quotas on a household basis, it can be extended. It fits in with the present restructuring of the agricultural production system, and it can better put into effect various forms of rural production responsibility systems. An example was in Yan'an Municipality, which has a total of 456 production brigades. Though three-fourths of them were located in fairly out-of-the-way ravines, nevertheless, inasmuch as water conservation methods required little investment, showed quick results and resulted in high yields, they were very much welcomed by the masses and every household in every village joined in. Beginning in 1977, the method was extended for a period of 3 years, and by 1980 was being practiced on 265,000 mu, each person farming an average of 1.7 mu of land for grain output that totaled 105 million jin, in 1978 rising to 130 million jin. Fourth, the system is able to make the most of soil fertility and set up the conditions for scientific farming. Not only does it hold back mud and retain water, conserving both soil and water, but it makes fullest use of soil fertility and lends itself to all-around application of the "Eight-point Charter for Agriculture," [soil improvement, rational application of fertilizer, water conservancy, improved seed strains, rational close planting, plant protection, field management and improvement of farm implements]. This farming system creates production conditions of relatively stable fertility for crops. For example, the furrow and ridge farming method has

broken up the rigid plowpan layer, deepened the cultivated layer, improved the sponginess of the soil, created large numbers of "micro-reservoirs" for crops to help protect seeldings, help their root development, help superior varieties realize their potential for increased yields, and help make full use of natural resources, such as water, heat, light and air. In addition, this farming method can give impetus to the development of farm mechanization. For example, use in the construction of furrows in a change from hand digging of trenches to tractor-drawn single-share plows, to tractor-drawn three row furrow-digging machines; in the sowing of seeds in a change from hand sowing to use of single-legged drills and animal-drawn twin-row planting machines; in the turning over and compacting of soil in a change from shoveling and hoeing to digging and rolling machines; in cultivation from hand-hoeing and deep digging to the use of animal-powered cultivators, etc.

Finally the article said that the loess highland area of Shaanxi Province that has yet to be brought under control is very great, and it will not be possible in the short term to carry out high speed capital construction of a substantial amount of farmland. In this situation, water and soil conservation farming methods have a lot of room for application. Therefore, they proposed the adaptation of general methods to local situations for the promotion of water and soil conservation farming methods in the loess highlands.

MORE EFFECTIVE LAND UTILIZATION IN NORTHERN SHAANXI REPORTED

Xi'an SHAANXI RIBAO in Chinese 16 Mar 82 pp 1, 3

[Article originally printed in NONGCUN GONGZUO TONGXIN [RURAL WORK BULLETIN]: "Carry Forward the Yan'an Spirit for Better Building of North Shaanxi Old Liberated Areas"]

[Excerpts] Yan'an and the Shaanxi-Gansu-Ningxia border area used to be the location of the CCP Central Committee and the main base of the Chinese people's liberation struggle. The great contribution that this area made to the Chinese revolution is world-renowned. The economic poverty and backwardness of this region is also a matter of general knowledge to all. How is the building of the old north Shaanxi liberated areas going today? How are the people of north Shaanxi living? These are matters about which the people of the entire country, and particularly old comrades who have lived and fought in north Shaanxi, are extremely concerned. The reply of the people of north Shaanxi to these questions is as follows: Since the 3rd Plenary Session [of the 11th Party Central Committee], as a result of the "correct line, suitable policies, and the people pulling together," and as a result of further improvements made in agricultural production conditions on a foundation of former construction done over a long period of time, agricultural production has won all-around bumper harvests for 3 consecutive years.

The Third Plenary Session was a great historical turn in the course of events. Beginning in 1979 agricultural production had three consecutive bumper harvests in northern Shaanxi's old liberated areas despite natural disasters, including drought, floods, insect pests and hailstones. In Yan'an Prefecture, 1979's grain output totaled 916 million jin, a 7.7 percent increase over 1978; in 1980, it was 1,406,000,000 jin, a 14.2 percent increase over 1979; and in 1981 summer grain output totaled 170 million jin, an 18 percent increase over 1979. Despite reduced output in the fall resulting from disasters, output for the year as a whole still totaled 950 million jin. In Yulin Prefecture, the 1979 grain output totaled 1,317,000,000 jin, a 7.13 percent increase over 1978. In 1980, despite the effects of natural disasters, output still totaled 1,233,000,000 jin. In 1981, output totaled 1.35 billion jin, an all-time high. Average amount of grain per capita was 800 jin in Yan'an Prefecture, and more than 700 jin in Yulin Prefecture. A considerable number of communes and brigades realized a "farming of three and a surplus of one." The masses eagerly sold their surplus grain to the state. In Yan'an Prefecture alone, last year households making sales of 10,000 jin in excess of quotas numbered 60. All-around development also occurred in forestry, livestock raising, and sideline occupations. Commune member economic income increased many times over. In Yan'an Prefecture, commune member per capita income averaged only 50 or 60 yuan in 1978, but amounted to 165 yuan in 1981. Some 100,000 peasant households repaid debts of many years standing. Since 1979, Yulin Prefecture commune member per capita income has averaged annual incremental increases of 35 percent, amounting to 150 yuan in 1981. The amount of rural savings deposits has increased each year, and the purchasing power of the masses has greatly increased.

How has it been possible for such large changes to have taken place within the short space of 3 years in the old liberated areas of Shaanxi Province?

First of all, the line, programs and policies in the wake of the Third Plenary Session have been a decisive factor. In addition, implementation of the 16 articles for liberalization of rural policies promulgated by the Shaanxi Provincial CCP Committee encouraged and supported commune members in the broadening of production avenues, development of the planting and aquatic products breeding industries, the plaiting industry, and such collective economically diversified and household sideline industries. Expansion of private plots and allocation of private firewood mountains, private forests and grasslands and deserts stimulated country market trade and enlivened the rural economy. The fairly early and fairly rapid development of agricultural production responsibility systems suited to local circumstances was particularly responsible for overcoming the bad practice of "eating out of a large common pot" that had long existed, and of directly linking the peasants' labor to the amount of compensation they should receive, thereby actively arousing enthusiasm for both collective operations by production teams and free operations by individual commune members. It revived and carried forward the Yan'an spirit of self-reliance and arduous struggle, and vigorously promoted development of a build-up of production.

Second was a program for the building of agricultural production suited to actual conditions prevailing in northern Shaanxi. In 1979, the Shaanxi Provincial CCP Committee summarized both positive and negative experiences to formulate a program for the building of agricultural production in northern Shaanxi, which was "simultaneous development of farming, forestry, and livestock raising, gradual changing of widespread farming for scant harvests to reduced farming for high yields and greater harvests; and while striving to realize self-sufficiency with some surplus in grain, to gradually build forestry and livestock industry bases."

In the change from sole emphasis on grain production to simultaneous development of farming, forestry and livestock raising, and in the change from widespread farming for scant harvests to reduced farming for high yields and greater harvests, during the past 3 years an area of more than 5.9 million mu has been newly forested, and more than 4 million mu of grasslands planted. This has gradually readjusted the proportional relationships within agriculture so that farming, forestry and livestock raising are organically linked, each playing its own role, one advancing the other to provide a definite foundation for restoring the ecological balance and assuring all-around development of farming, forestry and the livestock industry.

Third is active launching of agricultural science and technology work. Everywhere in northern Shaanxi, party and government leaders have assiduously put into effect the party's policies for intellectuals, and have intensified establishment of agricultural science and technology organizations and technical training work. They have readjusted crop patterns, adapting general methods to local situations to increase the proportions of broom corn millet, wheat, rice and pulse crops. They have bred and extended to cultivation fine varieties of hybrid corn, potatoes, millet and gaoliang; and they have reformed backward farming systems and growing methods. They have taken account of the aridity and low soil fertility that characterize northern Shaanxi to summarize and promote horizontal furrow planting methods; and ridge and furrow planting methods on riverlands, plains and flatlands; riverland wetland intercropping methods; and dryland plains area oil-bearing crops, pulses and grass fertile field methods. In places practicing the aforementioned "four methods" of farming fields, average yields per mu increased by between 50 and 150 percent over the customary former cultivation methods. In Yulin Prefecture, promotion of seedling propagation and transplanting techniques using plastic sheeting doubled average yields per mu as compared with the direct sowing of rice. In the leveling of fields for afforestation, aerial sowing for afforestation and the planting of grass, the mechanization of plant protection, and the introduction and propagation of superior varieties of domestic livestock and poultry as well, remarkable results were obtained. The introduction of fine-wool sheep, in particular, opened a new set of circumstances for the livestock industry of northern Shaanxi.

Fourth was fairly equitable use of special funds for the building of old liberated areas. Since 1979, we have applied the special funds that the Central Committee has annually allocated for construction of old liberated areas in northern Shaanxi mostly to support poor communes and brigades in changing basic agricultural production conditions, and in improving the livelihood of the masses. Management methods have also been formulated, and management organizations have been set up or specific persons assigned responsibility to assure that the special funds are used for special purposes. At the same time, state support has been combined with carrying forward the spirit of self-reliance to encourage common development by collectives and individuals; engineering methods have been combined with biological measures, the special funds for the construction of northern Shaanxi thereby playing an important role in changing poverty and hardship. During the past 3 years, both Yan'an and Yulin prefectures have done 600,000 mu of new capital construction of farmland, restructured and upgraded 500,000 mu, built 23 new reservoirs, 110 irrigation ditches and 805 pumping stations. Yan'an and Yulin prefectures plus Chunhua, Dianyi and Lin counties have erected 2,700 kilometers of electric power lines to solve problems in the use of electricity for five counties that had been without electricity. The electrically irrigated area has been increased by 170,000 mu.

The land area in use in the old liberated areas of Shaanxi Province amounts to 110 million mu, an average of 26 mu per capita. Land presently used for farming, for forests, and for grasslands amounts to one-half the land area in use.

In the future, the task of building production in northern Shaanxi must follow the principles of both providing the masses with sufficient clothing and food and carrying out modernized economic and cultural development, both promoting steady increases in agricultural production and gradually raising the standard of living of the masses, both broadening avenues of production, increasing collecting accumulations and commune members' economic income, and increasing and expanding reproduction capacity with the building of forestry and livestock industry bases with all possible speed while correspondingly developing industrial production.

We plan, first of all, to achieve the "1, 9, 8, 5" struggle objectives that Comrade Hu Yaobang has proposed to the people of Shaanxi. This means the realization by 1985 or a little longer of 1 large livestock animal, 9 mu of forests or grassland, 800 jin of grain and 5 sheep or goats per capita.

SHANDONG

TECHNIQUE FOR INCREASING SINGLE-CROP COTTON PRODUCTION

Jinan DAZHONG RIBAO in Chinese 2 Apr 82 p 2

[Article by Shandong Academy of Agriculture: "The Cultivation of Seedlings in Nursery Pots Is the Key Technique for Increasing Single-crop Cotton Production"]

[Text] The technique of cultivating cotton seedlings in nursery pots is a key technique to increase the single-crop cotton production and the quality of the fiber. Whether in coastal and the cotton producing eastern part of the province where the frost-free period is relatively short and where early spring temperature warms up slowly, or in the cotton producing areas in the southwestern part of the province where the frost-free period is relatively long and warm temperatures return rather early in spring, whether the soil is rich in saline-alkali or whether it is clayey ground or sandy and loam, the adoption of this technique has resulted in increased cotton production, early maturity and better quality. This phenomenon of increased production and early maturity is particularly noticeable in clayey soil, and sandy loam and massif areas where cotton seedlings emerge late. However, this technique for increasing cotton production had not been widely adopted for a long period of time. It was not until the 3d Plenary Session of the 11th Party Central Committee when the enthusiasm of the cotton farmers to learn and to adopt scientific methods was unprecedentedly raised that the technique of cultivating seedlings in nursery pots achieved greater development. In 1981, cotton fields that have adopted the method of cultivating and transplanting potted seedlings reached 1.2 million mu throughout the province and cotton production generally increased by 20 percent. The economic benefit of transplanting cotton was also higher than that of cotton directly planted onto the field. It is, therefore, of paramount importance to promote the technique of cultivating potted seedlings in nurseries so as to achieve bumper cotton harvest to meet the need to stabilize the acreage of cotton fields and to increase single-crop as well as the total cotton output.

Why is the technique of cultivating seedlings in nurseries and transplanting them a key to increasing single-crop production? The chief reasons are as follows:

(1) The growth of cotton is not limited to fixed periods. However, due to the brief frost-free period in the cotton producing areas in our province, the flowering period for cotton planted directly onto the field usually begins around 15 July and lasts for only about 60 days. This puts a limit on the

amount of cotton production. As for transplanted cotton seedlings, the earlier they are planted, the sooner they emerge. Generally, the flowering period, which comes at the end of June and early July, may be extended for about 10 days so that the number of early cotton bolls and the total number of cotton bolls per plant is dramatically increased, usually by about 15 percent before frost sets in. At this time, because a large portion of the cotton bolls in our province grows during the period when temperature, humidity and light illumination are most suitable for cotton growth and cultivation, the weight of the cotton bolls is in general heavier (an increase of about 0.15 gram per boll), the fiber matures well and the quality better.

(2) Cultivation of cotton seedlings in nursery pots also ensures even emergence of seedlings. Usually the low temperatures and dry weather in the spring in the cotton producing areas in our province, cause a rather large portion of the seedlings directly planted onto the field to emerge unevenly, especially on clayey soil and soil that is rich in saline-alkali where there is a predominant absence and uneven growth of cotton seedlings. This irregular degree of growth affects the yield of cotton production. By cultivating seedlings in nursery pots before transplanting them, it is possible to ensure their healthy growth because the pot soil is rich in nutrient, and the seedbed provides adequate temperature and moisture. Besides, at the time of transplanting, one can weed out the weak and unhealthy seedlings, enabling a healthy and even growth of the seedlings. By the time these seedlings are transplanted, the stems are already ligninized, more alkali tolerant and adverse effect resistant, sustaining a higher rate of survival, and ensuring an even growth of the entire shoots and cotton seedling. Furthermore, at the time of transplant, these seedlings can be easily planted in equal distance thereby ensuring a balanced nutritive area per plant, which is conducive to an even growth of each plant in between individual spaces. This also helps achieve a balanced increase in production.

(3) The technique of transplanting potted seedlings ensures strong shoots and steady growth. The breaking of the tap root at the time of transplant stimulates the growth of lateral roots, increases the number of roots in the cultivated layer, strengthens the plant's ability to absorb nutrients, thus promoting a healthy growth of the cotton plants. Furthermore, the transplanting of pot-cultivated seedlings can be transplanted earlier than the direct sowing, moving ahead the growing period by about 15 days. The earlier germination of the seedlings and the relatively low temperature prevailing in the early stage of development ensures their steady and healthy growth. Experiments bear out the fact that the height of the first fruiting branch of transplanted cotton plants is generally more than one centimeter lower than that of cotton plants directly planted onto the field. The length of the main stem is reduced by about half a centimeter in average while the height of the plant is reduced by about 5 centimeters presenting a more compact shape. In general, those cotton plants in our province that are transplanted from seedlings before the arrival of the rainy season yield more bolls per plant than those directly planted onto the field. Because of the even distribution of nutrition in the cotton plant, the amount of nutrition that reaches the reproductive organ is correspondingly larger than the amount that goes to the growing point of the plant, thereby restraining the plant's excessive growth, which easily happens in a season when both rain and heat occur simultaneously. By postponing the chance of excessive growth from happening, and by increasing the level of

photosynthesis, the shedding of cotton squares and bolls would be reduced, thus increasing the budding in the middle and lower parts of the cotton plant.

Experiences inthe transplanting of potted seedlings dictate that we should have a firm grasp of the following questions in techniques:

(1) Quality of nursery pots and proper management of seedbeds. The potting soil must be rich to promote the healthy growth of the seedlings. Generally, mellow soil, mixed with 20 percent of quality decomposed barnyard manure should be used. The pots should be of the proper size. If the pots are too large, the usage rate of seedbed is reduced. If they are too small, the seedlings would not grow well. As a rule, the pots should be 6 centimeters in diameter and between 8 to 10 centimeters in height. The most important requirement in the management of seedbeds is to maintain a proper temperature. Before potting, the seedbeds should be well watered. The seeds should be carefully selected and soaked. The film for mulching should not be removed from the time the seeds are planted to the time when they begin to sprout. The seedbeds should be kept at a moderately high temperature to promote sprouting. After sprouting, care should be taken to remove the film and to cull the seedlings. The temperature of the seedbeds should be maintained at about 25°C.

(2) Superior transplanting methods. Superior methods of transplanting seedlings shortens the period of their controlled growth, a key to ensuring healthy growth, early maturation and high yield. Proper transplanting requires first, that it be undertaken at the proper time. Generally, it is around the end of April when the temperature is between 17 and 18°C steady. Second, transplanting requires delicate and careful handling that damage to the roots can be reduced to the minimum. Large and small seedlings should be separately transplanted. The seedlings should be planted at a proper depth, because if it is too deep, the temperature of the oil would be too low while if it is to shallow the pots would easily dry up hindering the sprouting. Third, thoroughly water the "settling water" to completely wet the potting soil so that it could be well mixed in with the soil in the large field later. However, if it is too early to transplant, overwatering would lower the temperature of the soil and prolong the time to revive the seedlings. Fourth, focusing on fertilization. Before transplanting, bacterial manure or chemical fertilizers may be applied to promote sprouting. Fifth, the soil should be loosened between the plants and between the rows of plants to raise the temperature of the soil.

(3) Strengthening post-transplanting management. Cotton plants transplanted from nursery pots develop earlier and have shallower roots, are more susceptible to lodging and premature wilting. For this reason, advance attention must be paid to transplanted, as opposed to directly planted cotton plants, especially during the intermediate growing period. During this intermediate cropping period, fertilizer and water must be properly controlled to prevent premature wilting. The work of preparing the soil and drainage must be done in advance to prevent lodging and rotting. The rotted bolls must be culled and disposed of promptly.

BRIEFS

CORN BORER PEST--This year a large number of corn borers will probably emerge in Shandong Province. Various localities should quickly adopt prevention measures to ensure the safety of cornfields. Since the temperatures in the past winter-spring period were higher, there are 30 to 50 percent more corn borers in the province than usual. BRIEFS

SUMMER AGRICULTURAL PRODUCTION--Summer agricultural production is in full swing in Shanghai's suburban areas. By 21 May, more than 470,000 mu of barley has been harvested and 250,000 mu of early rice and 200,000 mu of cotton transplanted. Field management for the remaining 500,000 mu of cotton has been intensified. [Shanghai City Service in Mandarin 1130 GMT 22 May 82 OW]

DRYLAND FARMING TECHNIQUES PROPOSED

Taiyuan SHANXI RIBAO in Chinese 5 Feb 82 p 1

[Article by Liu Bosheng [0491 0130 3932]: "Need for North China Region to Take Organic Dryland Crop Route. Zhang Qinwen [1728 3084 2429] Makes This New Proposal, Which Receives Serious Attention of Provincial and National Units Concerned"]

[Text] In North China, and particularly in a place like Shanxi in which "9 out of 10 years are dry," as a strategic matter, what should be the main focus of attention in development of agricultural production? For a long time people have generally believed the focus should be on water to combat drought. A scientist in the province, Comrade Zhang Qinwen, has put forward a different proposal. In an academic treatise published in 1981, "Organic Dryland Crops Agricultural Strategy," he pointed out that the technical strategy for development of agriculture in the northern regions of China at the present stage must be an organic dryland crop agricultural strategy.

The so-called organic dryland crop agricultural strategy means that in areas in which development of water conservancy is currently difficult, there should be leveling of the soil to conserve water and soil, and increased fertilization with organic fertilizer, paired with a series of farming methods to combat drought for the building of a farming system that interrelates use and nurture of the land, rather than insistence on an agricultural strategy that employs expensive irrigation. His goal is to build an equitable and highly efficient ecological system and to preserve an orderly material cycle and energy exchange in the agricultural production process, the land thereby becoming more fertile the more it is farmed to increase yields per unit of area.

Comrade Zhang Qinwen is a researcher in the Rural Economy Agricultural Systems Engineering Research Office of the Provincial Agricultural Zoning Commission, and he has worked for more than 20 years on forestry and agriculture in Youyu County. In the process of long work experience and investigation and study, he has accumulated a large amount of data, and he deeply feels that a large number of units do not attach sufficiently serious importance to soil improvement and build-up of soil fertility. Capital construction of farmland frequently emphasizes only changes in form and ignores improvements of an essential kind of a build-up of soil fertility. Attention goes only to the building of water conservancy projects and emphasis on water to irrigate the land to the neglect of fundamental improvements in the structural properties of the soil and the adoption of farming practices to combat drought. A large body of facts demonstrates that impoverished soil is one of the main reasons for the low yields and backwardness of agriculture, and for the frequency of natural disasters in northern regions of China. Hopes that reliance on construction of water conservancy can fundamentally solve drought problems are currently difficult to realize. When water is available, emphasis should naturally be placed on water, but when the "water route" is not open, it is necessary to take the "dry road," i.e., to adopt the strategy of organic dryland crop agriculture, taking the road of improving the soil and using the soil to store water.

Following publication of Comrade Zhang Qinwen's thesis, "Organic Dryland Crops Agricultural Strategy," not only did it receive the serious attention of leadership comrades in units concerned in Shanxi Province, but it also received the serious attention of units concerned and leadership comrades in the central government and in some provinces. Publications or reference materials published by the State Agricultural Commission, the National Agricultural Zoning Commission, the Agricultural Modernization Research Committee of the Chinese Academy of Agricultural Sciences, the Chinese Agricultural Economics Society and the Agricultural Economics Institute of the Chinese Academy of Social Sciences all either published in full or excerpted for publication Comrade Zhang Qinwen's treatise.

ADMINISTRATIVE METHODS FOR ENHANCING FARM MACHINE EFFECTIVENESS EXPLORED

Taiyuan SHANXI RIBAO in Chinese 1 Feb 82 p 2

[Article by Pin Zeng [0756 1073] and Li Hua [2621 5478]: "Good Farm Machinery Management to Promote Agricultural Development. Province's Farm Machinery System Enhances and Improves System of Responsibility for Farm Machinery in Four Ways"]

[Text] In order to assure new advances this year in farm machinery work, the broad masses of cadres and workers in Shanxi Province's farm machinery system have actively mobilized to enhance and perfect the system of responsibility for farm machinery in four ways.

The provincial conference for exchanges of experiences on the system of responsibility for farm machinery management and production convened in early December 1981 gave very great impetus to the farm machinery front. In the process of reflecting on and summarizing the year's work, the broad masses of farm machinery workers experiences a keen sense of the need to enhance and improve systems of responsibility for farm machinery and production in a new situation. They studied and discussed the spirit of the Provincial Farm Machinery Conference, and focused, in a planned and goal-oriented way, on the weak links in practice of systems of responsibility for production to make gradual improvements in them.

First was strengthening of leadership and heightening of perceptions. Leadership comrades in farm machinery units in Pu County and in Zuoyun and Youyu counties led work teams of varying numbers of people into the countryside where they conducted typical case indoctrination to solve problems in perception. They used the mental reservations on the part of some communes and brigades during the past year that have resulted in fears that collectives would fail while individuals would prosper, bringing about destruction of farm implements, which hurt farming. From the year-end honoring of contracts, they learned lessons of experience for deciding on this year's system of responsibility.

Second was tailored guidance. Acting on requirements from the Provincial Farm Machinery Bureau, farm machinery management units at all levels in Xin County worked out specific criteria for selection of forms of a system of responsibility in specific situations, which were explained and publicized at the grassroots level. Comrades in charge of farm machinery units in Pingding, Xiyang and Heshun counties also went from village to village in the company of farm machinery management personnel from communes to give briefings on various forms and characteristics of systems of responsibility for farm machinery, and to give tailored guidance.

Third was signing of equitable contracts. In view of problems that cropped up in 1981 in the practice of systems of responsibility, when contracts were signed this year, in some places both parties discussed in detail, article by article and amount of money by amount of money, the specific content of "contracting production or work quotas, fixing amounts and giving rewards" regarding amounts, how to assure farmland operations, launching of economic diversification, how to maintain farm implements in good mechanical condition, and how various kinds of accidents were to be handled. They reached agreement on these matters, making the work of reducing or avoiding disputes that might arise a priority matter.

Fourth, farm machinery companies at all levels, and county farm machinery repair units, as well as farm machinery institutes, technical promotion units, safety control units and training units, all began to study measures to expand the scope of vocational activities, to streamline organizations, and to increase efficiency, as well as to solve the problem of personnel in excess of needs. In addition was diligent implementation of the unit's work criteria, seeking to find good ways to closely combine the welfare of staff and workers with the welfare of the collective. The broad masses of staff and workers said happily that coming to grips with the major matter of systems of responsibility at the beginning of a new [lunar] new year was a fine start.

SICHUAN

BRIEFS

RECORD SICHUAN PIG PRODUCTION--Although Sichuan Province suffered from disastrous floods last year, the province's pig production and sales broke four of the highest records in history. According to the Sichuan Provincial Statistical Bureau, the province marketed 32 million pigs last year, the state purchased 19.3 million pigs. Both figures topped those of the peak year, 1980. Last year the province's urban inhabitants consumed an average of 56.1 jin of pork per person, 0.9 jin less than the year before. But the province's 80 million peasants consumed an average of 22.7 jin of pork per person last year, compared with 22.1 jin the previous year. The average consumption of pork for the entire population of the province, both urban and rural, was 26.8 jin per person last year, an increase of 0.3 jin over the previous year. STATUS REPORT ON XINJIANG RECLAMATION SYSTEM PROVIDED

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 1, 1982 p 5

[Article: "Xinjiang Production and Construction Army Wins New Victories in All Around Bumper Harvest and in Turning Losses Into Profits"]

[Text] On New Year's eve 1982, the Xinjiang production and construction army located in the northwestern reaches of the motherland transmitted the inspiring news of victory in winning an all around bumper harvest and in turning losses into profits.

Thanks to the efforts of the reclamation area's broad masses of cadres and employees, the reclamation area triumphed over natural disasters of drought and hailstorms in 1981 to win a bumper harvest of rare proportions. Despite a 600,000 mu cut in the previous year's grain growing area, output increased by 3 percent over the bumper previous year and is expected to reach 1.9 billion jin. The cotton growing area increased by 300,000 mu and cotton yields per unit of area increased as well, to produce a ginned cotton output totaling 1 million dan, a 43 percent increase over the previous year. Fairly great increases also took place in output of oil-bearing crops, output totaling 900,000 dan, a 12.5 percent increase over the previous year. Hops output totaled more than 4,000 tons, a 1.5 fold increase over the previous year. Both the number of livestock in inventory, and the output and output value of various livestock products increased over the previous year. Gross output value of industry reached 770 million yuan, an 8.4 percent increase over the previous year. Of the 28 different major industrial goods included in the state plan, 21 either fulfilled or overfulfilled plan, and output value of 9 industrial products that use farm or livestock products as raw materials increased by more than 30 percent over last year. Results foretell a turning of losses into profits for the army as a whole for removal of the stigma of more than 10 consecutive years of losses.

Since the Third Plenary Session of the 11th Party Central Committee, the Xinjiang Reclamation Area has conscientiously put into effect the CCP Central Committee's programs and policies and has taken three great strides in 3 years to bring about major changes very rapidly in the reclamation area. In 1981 in implementing the programs and policies of the CCP Central Committee, they devoted attention mostly to the following several tasks.

First was to carry out programs for readjustment of the national economy with vigorous readjustment of the industrial structure. They took vigorous action to increase yields per unit of area and assure total output, suitably cutting back the grain crop growing area while increasing the growing area for various economic crops of high economic value, earnings from agricultural production thereby increasing tremendously. From the 300,000 mu increase in the cotton growing area alone, total earnings from agricultural production increased by more than 15 million yuan.

Second, they revived and developed integrated agricultural, industrial, and commercial operations and economic collectives. The army had formerly instituted integrated industrial, agricultural, and commercial operations for great increases in economic results. During the past several years they strove to overcome the damage caused by the 10-year period of turmoil, adapted general methods to local situations for development of industrial production, and followed a course of integrated agricultural, industrial, and commercial operations. In 1981, their profits from industry and transportation alone amounted to more than 55 million yuan.

Third, they promoted various forms of production responsibility systems. In 1979, they began to institute a system of sole responsibility for finances on farms, and a system of "three fixeds and one reward" for company-size units. In 1980 they tried out accounting by companies, fixing output quotas based on groups, and placing responsibility on specific people, and in 1981 numerous regimental farms and company-size units acted under unified administration in the further promotion of the fixing of output quotas based on groups and the linking of the calculation of rewards and penalties to output. Some promoted various forms of linking professional wages and variable wages to link fairly closely together employees earnings and the fruits of labor to arouse enthusiasm among employees.

Fourth, they did a solid job of promoting new scientific techniques. They instituted reasonably close planting of all crops, and increased by more than 10 percent the number of wheat and cotton plants in a full stand. All regimental farms improved fertilizing methods, each of them using a layer-by-layer deep application method. They extended use of the new technique of plastic mulching of cotton over more than 20,000 mu for ginned cotton yields of more than 190 jin per mu, an output increase of 30 to 50 percent.

GREATLY INCREASED SOYBEAN PRODUCTION URGED

Kunming YUNNAN RIBAO in Chinese 18 Mar 82 p 1

[Article: "Great Production of Soybeans"]

[Text] Great production of soybeans, white kidney beans and miscellaneous other pulses, striving for fairly tremendous increase this year in production of pulses, is an important task in spring-sown grain and pulse production, and is also a major matter in the development of economic diversification. The method proposed by Zhaotong County following analysis of the county's historical soybean production situation and present difficulties of the masses in getting products to eat made of soybeans is a good one in that it requires efforts to achieve manifold increases in soybean output this year and to take action on the basis of these increased production figures. Great production of soybeans now required just such determination and just such action!

Soybeans are a necessity in the lives of both city and country people. As people's livelihoods improve, mass requirements for soybean products steadily increase. However, in many places soybean output has not been restored to its all-time high. In many places the difficulties that city and country people experience in getting soybean products to eat are a long way from a solution. The famous Zhaotong soy sauce is hard to buy, and the famous Shibing dried beancurd, Lu'nan beancurd in thick gravy, Yuqi fried beancurd in thick gravy, Yimen fermented green soybeans and Kunming Taihe fermented soybeans are all hard to buy. Great production of soybeans has already become a major matter bearing on the livelihood of the masses. Advantages in developing soybeans are numerous as well. Given the fairly high procurement price paid for soybeans, peasant income will be increased. Root nodule bacteria on soybeans, which can fix nitrogen, can increase soil fertility to promote growth of other crops and lower production costs. When large quantities of soybeans are available, they can provide large amounts of raw materials to state and collectively-owned units for food processing, increasing state and collective income. For the state, the collective, and individual peasants, large-scale production of soybeans is necessary.

Yunnan Province has conditions favoring development of soybean production. Most of the province's more than 20 million mu of drylands can be used for the intercropping of soybeans or for planting them as a single crop. However, as a result of the reduction that has taken place during the past several years in the area on which soybeans are planted as a single crop, plus some improper farming methods, intercropping and interplanting of soybeans has been impaired. Now conditions exist for expansion of the area on which soybeans are grown as a single crop, as well as to take commensurate action to increase the quantity of intercropping and interplanting of soybeans. Still another important situation is that the broad masses of peasants in most areas are accustomed to and experienced in the growing of soybeans, and are currently enthusiastic about growing more and better soybeans. The key lies in leaders devoting serious attention to this problem and genuinely taking soybean production in hand as a major matter for increasing peasant income, developing economic diversification, and improving the livelihood of the masses, making plans, and, like Zhaotong County, taking several genuinely effective vigorous actions for gradual implementation echelon by echelon and unit by unit. These actions include the formulation of plans, designation of areas for the growing of soybeans as a single crop, for intercropping, and on earth embankments between fields, establishment of responsibility systems, the signing of procurement contracts between grain units and production teams and commune members, helping with the hauling of seeds, extension of advanced techniques, etc.

LINFEN PREFECTURE SPEEDS UP SUGAR CANE PRODUCTION

Kunming YUNNAN RIBAO in Chinese 1 Apr 82 p 2

[Article by Yang Yiji [2799 3558 1015]: "Linfen Prefecture Accelerates the Rate of Sugar Cane Production"]

[Text] In 1981, Linfen Prefecture achieved the highest record in sugar cane production in history. Sugar cane output for 1981 came to 152,000 tons, or a 36.4 percent increase over 1980 while sugar production reached 12,000 tons, or a 29 percent increase over 1980. Summarizing their experience in increasing sugar cane production, those in leadership positions in the party and the government in Linfen Prefecture have gone one step further to strengthen their leadership, increase single-crop sugar cane production and adequately enlarge the production area so as to win a still greater development in sugar cane production.

Linfen Prefecture holds a favorable position in sugar cane production. There are 8 counties, 79 communes (townships), over 500 production brigades and 10 state-operated farms in Linfen Prefecture, all of which are well suited to planting sugar cane. During the past year, those in leadership positions in the party and the government, in an all-out effort to implement the guiding principle of "absolutely not relaxing efforts in grain production and to develop diversified economy in a positive manner," took full advantage of the favorable natural local conditions in making sugar cane a mainstay production. First, in areas suitable for sugar cane cultivation and acting on the principle of "adopting methods suitable for local conditions, exercising a proper degree of centralization, coordinating planning and selecting the proper projects for development," they readjusted the distribution of crops and increased the acreage for sugar cane cultivation to some 54,400 mu, or 8.7 percent over the figure for the previous year. In order to resolve the conflict between grain and sugar cane production, the amount of agricultural tax in kind should be adjusted and reduced in sugar cane producing areas, the policy of "establishing a link between sugar cane and grain production, setting up base figures and offering bonuses for production in excess of the production quota" should be thoroughly carried out and the positive attitude of commune members to develop sugar cane enterprises so that the size of the producing areas may be stabilized, should be mobilized, making these producing areas reliable sugar cane production bases. Assistance should also be provided to the 1,300 plus sugar cane production brigades to set up various forms of the production responsibility system to suit their actual conditions. A bonus system should be set up to motivate the positive attitude of the cadres, technical personnel and the sugar cane production supervisors of the communes and brigades so that they may unite as one in the development of sugar cane production.

Over a number of years, sugar cane production in Linfen Prefecture has been characterized by low productivity, poor management, a lack of variety and low single-crop production and yield. During the past year, while the acreage for sugar cane production was being expanded, efforts were made to increase single-crop production. The agricultural departments and sugar mills in the various counties assigned a number of technical cadres to conduct on-the-spot conferences to train sugar cane production supervisors and to conduct high yield model plots to assist commune members to achieve higher standards in scientific production of sugar cane. There are in total 2,300 mu of high yield model sugar cane fields throughout the prefecture. Improvement was made on cultivation methods. Summer, autumn and winter sugar cane production was extended by 400, 1,400 and 1,200 mu respectively. The conflict arising from the competition for labor, water and the planting seasons between sugar cane and grain production was thus considerably eased. Furthermore, efforts were made to popularize improved varieties, raise the quality and quantity of the crop, intertill and prepare the soil at the proper time, increase the application of fertilizers, strengthen management and prevent and control insect diseases. Thanks to the early arrival of and even spring rainfall last year, sugar cane growth was thriving throughout the prefecture. The single crop per unit yield throughout the prefecture came to 2.87 tons, or a 14.7 percent increase over the figure for the previous year. Furthermore, a number of high yield model plots produced single crops of more than 10 tons per unit.

At the present time, sugar cane farmers in various areas are elated over the bumper harvests and are busily engaged in the peak season for the felling, transporting and pressing of sugar cane. During the first part of March, throughout the prefecture, 29,400 tons of sugar cane has been pressed and 6,900 tons of sugar has been produced. While close attention is being paid to the felling of sugar cane, the various areas are also summarizing their experience in achieving increased production, planning sugar cane production for this year and grasping spring sugar cane crop in time in order to win a still greater bumper harvest of sugar cane. The communes and brigades have pledged to direct their efforts toward increasing the single crop high yield of sugar cane, expanding sugar cane cultivation area; up to 60,000 mu for this year is in the plan, including 20,000 mu for the spring sugar cane crop. According to incomplete statistics, some 7,000 mu had already been planted by March 10.

LIVESTOCK EPIDEMIC PREVENTION, CONTROL URGED

Kunming YUNNAN RIBAO in Chinese 18 Mar 82 p 1

[Article: "Take Firmly in Hand Spring Prevention and Control of the Spread of Epidemic Diseases in Livestock. Provincial People's Government Issues Notice"]

[Text] On 11 March, the Provincial People's Government issued an "Urgent Notice on Taking Firmly in Hand Spring Prevention and Control of the Spread of Epidemic Diseases in Livestock," requiring that all jurisdictions diligently take firmly in hand prevention of springtime epidemics among livestock and diligently control the spread of epidemic diseases.

The notice said that springtime epidemic prevention work is already underway in Yunnan Province. Some places have taken this work firmly in hand; measures taken have been vigorous, progress has been fairly rapid, and the number of inoculations given fairly high. However, development has been very unbalanced, and as of the end of February, only 30-odd counties in the province had completed their springtime prevention work. In most places, progress has been slow, and the number of inoculations given fairly low. Another 10-odd counties have not gotten underway. March is a key period for conducting spring epidemic prevention inoculation of livestock, and the opportunity cannot be missed. Consequently all jurisdictions are required to conscientiously perform the following tasks.

1. All levels of government are to diligently strengthen leadership of this work, assign a responsible comrade to take charge of it, immediately examine progress that has been made in spring epidemic prevention work, focus on existing problems, and take energetic action. All levels of livestock units must vigorously attend to and conscientiously take in hand spring epidemic prevention work.

2. In places in which the work is being done poorly or has yet to get underway, vocational units are to allocate personnel, expenses and pharmaceuticals necessary for springtime epidemic prevention work to help these places do a good job of springtime epidemic prevention. Places in which genuine hardships exist should allocate needed funds in accordance with pertinent regulations, and practice

dividing up the work and assigning tasks to individuals, bonuses being given for overfulfillment. Needles should be used to assure completion of the province's 70 percent quota for epidemic prevention inoculations.

3. Places that have completed livestock epidemic prevention work should organize booster inoculations and carry out market quarantine work to control the spread of epidemic diseases.

PROVINCIAL PLANS, METHODS OF IMPROVING RED SOILS REVEALED

Kunming YUNNAN RIBAO in Chinese 25 Mar 82 p 1

[Article by Xue Qirong [5641 0796 2837]: "Improve Red Soil To Hasten Agricultural Development--A Summary of Experiences of Some Areas in Improving Red Soil"]

[Text] Recently at the Provincial Conference for the Spread of Red Soil Improvement Techniques, which was jointly convened by the Provincial Science Commission, the Provincial Agricultural Commission, the Provincial Department of Agriculture, and the Provincial Academy of Agricultural Sciences, it was decided that this year 1 million mu of low yield red soil farmland is to be improved, and before 1985, 5 million mu of red soil farmland throughout the province is to be improved little by little.

What can be done to improve red soil? Some areas' experiences in the improvement of red soil are as follows:

Sensible Phosphate Fertilization. In most red soil regions of Yunnan Province, soil phosphate content is low, and effective phosphate directly usable by crops is even lower; therefore, increased fertilization with phosphate is urgently required as part of the improvement of red soil, solving the effective supply of phosphate at the same time. In the course of their long experience in production and research, agricultural scientists have figured out some sensible techniques for fertilization with phosphate. 1) Increased fertilization of low fertility red soil with phosphate fertilizer. The Soil Fertility Institute of the Provincial Academy of Agricultural Sciences conducted experiments at Longquan Commune in Kunming, which showed that for every 50 kilograms of phosphate fertilizer applied to low fertility red soils, corn yields increased by 439 jin. Use of the same amount of phosphate fertilizer on highly fertile red soils produced yield increases of only 105 jin of corn. Phosphate fertilizer experiments conducted at other places also showed that following: On most low fertility red soils, for every 50 kilograms of phosphate fertilizer used, effectiveness in increasing yields was approximately that of 4,000 jin of barnyard manure, corn yields increasing by from 100 to 200 jin. 2) Concentrated use of phosphate fertilizer for base fertility. When used as a base fertilizer, phosphate concentrates in the crop rhizosphere, reducing the contact surface of the phosphate and soil particles for an increase in utilization rate. Experimental statistics show that when phosphate fertilizer is spread, its utilization rate is a general 10 to 20 percent, when applied in concentrations, its utilization rate may reach as high as 40 to 60 percent. 3) Use of phosphate fertilizer and organic fertilizer in combination. Use of this method can reduce the active iron and aluminum content of red soil, promote release of soil phosphate, and increase the effectiveness of phosphate fertilizer.

Active Expansion of the Growing of Green Manure. Production experiences everywhere have shown that use of green manure on red soil, particularly on low fertility red soil, can remarkably increase grain yields. Statistics from the Soil Fertility Institute of the Provincial Academy of Agricultural Sciences show that when between 1,000 to 4,000 jin of green manure was applied to low fertility red soil dryland fields, corn yields increased by from 4.3 to 36.1 percent for average yield increases of 19.7 percent. For every 1,000 jin of green manure applied to paddy fields, paddy yields increased from 57.3 jin to 133.5 jin, for an average increase of 94.6 jin per mu.

Adaptation of General Methods to Local Situations in the Use of Lime and Trace Element Fertilizer. The use of lime or calcareous material to improve red soil has been an effective soil improvement method used by the masses for many years. Experimental statistics show that the spreading of from 500 to 1,500 jin of lime per mu on red soil of average acidity increased corn yields by from 66 to 236 jin. With the application of 3,000 jin per mu of lime, soil acidity decreased; effective phosphate increased; soil water retention and fertility increased; and corn yields increased by more than 100 jin. However, the spreading of lime or calcareous material to improve red soil requires adaptation of general methods to local situations. In places where mostly lime is to be applied, a first application of from 2,000 to 4,000 jin per mu is suitable, followed by a second application 3 to 5 years later. Places using mostly calcareous material (white sand) should apply from 10,000 to 15,000 jin per mu the first time. If lime is well spread, there is no need to mix lime or white sand with phosphate fertilizer as a covering fertilizer; instead the lime can be applied along with barnyard manure. In some of the newly reclaimed areas of Yunnan Province, sandy red soil effective content of trace elements, such as copper, boron and zinc, is low, and if excessive amounts of white sand or calcium-manganese-phosphate fertilizer is applied, effective fertility may be easily reduced. Attention must be given the increase in trace elements. Experiments have shown that use of 3 jin per mu of zinc sulfate as a base fertilizer or use of a from 0.15 to 0.2 solution of zinc sulfate to spray leaf surfaces two or three times can increase corn yields by 100 to 200 jin per mu.

Deep Plowing and Mixing In of Soil Brought from Elsewhere. Some places in Yunnan Province have practiced the digging of large pits for use in deep plowing and the mixing in of foreign soil, both of which have shown fine results in improving red soil. Deep plowing and the addition of foreign soil mostly make the friable surface horizon thicker, improve the red soil's physical properties, and regulate the soil's moisture, air and temperature conditions, creating conditions for the transformation of nutrients. According to analysis of equally stiff Milexi soil, the per unit weight of soil to which foreign soil had been added was lighter, its porosity greater, and its moisture content higher than that of either soil plowed by oxen or soil to which no foreign soil had been added. Its effective nutrients also showed remarkable changes, and the thickness of the cultivated horizon was increased.

Reform of the Farming System. Sensible interplanting and intercropping plus crop rotation in a combination of use and nurture of the soil to make full use of the superior natural conditions and latent soil fertility that Yunnan's red soils offer are important links in increasing crop yields, and they are also major ways in which to increase red soil fertility. Experiences resulting from demonstration crop system reform on three red soil plots in Wenshanzhou show that given the same care, intercropping can produce yield increases ranging from 120 to 200 jin per mu more than the growing of a single crop. All jurisdictions can adapt general methods to local situations for the intercropping of long and short stem crops, and for the intercropping of grain, edible oil, pulse, and green manure crops to increase the multiple crop index and to increase ground cover, with benefits for regulation of soil temperatures, humidity and nutrients, to achieve a combination of nurture and use, increased soil fertility, and consistently high yields.

BRIEFS

FOOD, GOODS SUPPLIES--Since the beginning of this year, the supplies of nonstaple food and daily-use consumer goods in Yunnan Province have been better than last year. The supply of vegetables is better than last year. According to the statistics of Kunming, Baoshan and Qujing, the quantity of vegetables on sale in the market and the variety of vegetables are both greater than last year. In the first quarter of this year, the province purchased some 748,000 pigs, some 39,000 pigs more than in the corresponding period last year. According to statistics, the number of watches, TV sets and the amount of ginned cotton sold in the province in the first quarter of this year was 48, 35 and 50 percent more than in the same period last year respectively. The supply of small commodities in the province is better than last year. The number of contracts for small commodities signed in the province in the first half of this year was 70 percent more than in the same period last year. There are more small commodities which the masses need, including cotton thread, sewing needles and combs, on sale in the market than last year. The proportion of small commodities to all commodities has increased from 32 percent last year to 35.7 percent now. Matches which were in short supply last year have been in ample supply since the beginning of this year. The amount of matches supplied in the first quarter was 10.6 percent more than in the corresponding period last year. [Kunming Yunnan Provincial Service in Mandarin 1100 GMT 21 May 82 HK]

SUGARCANE PROCUREMENT--Yunnan Province has reaped a good harvest of sugarcane this year. As of 26 May, the province had procured 220,000 tons of sugar, or 40,000 tons more than last year. The province's total sugar output this year has hit an all-time high. By mid-May, the province had produced over 245,000 tons of sugar, or 28 percent more than in the previous year. [OW041437 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 31 May 82 OW]

I. GENERAL INFORMATION

SYMPOSIUM ON GRAIN DRYING TECHNIQUES HELD

Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 1, 1982 p 28

[Article: "National Symposium on Grain Drying Techniques Held in Yongchuan"]

[Text] The National Symposium on Grain Drying Techniques sponsored by the Special Committee on Harvest Processing Machinery of the Chinese Farm Machinery Society was held 1 to 5 December 1981 in Yongchuan County, Sichuan Province. The meeting discussed the direction and the road of development of our nation's drying techniques, energy needed for drying, drying techniques, and the study of structural parameters of machinery parts.

According to statistics compiled by the Ministry of Agriculture, in ordinary years, several billion jin of grains are damaged by mildew caused by rain throughout the nation. In serious years, more than 10 billion jin are damaged a year. Overcast and rain occur frequently during the harvesting seasons in the south. The monthly average duration of rainfall in some localities is more than 20 days. The relative humidity is above 80 percent, and the temperature rises to 27-28 degrees centigrade. Loss of food grains due to mildew is high. The meeting expressed the view that the southern provinces should popularize key regions of grain drying machinery. The northern regions can also correspondingly develop grain drying techniques by suiting measures to local circumstances based on economic conditions and the climate of local farm villages. The Northeast is the major commercial food grain base. Grains are gathered on the drying fields in a concentrated manner during the harvesting season. Manual turning and drying require 50 to 60 percent of the labor force. Equipment for preliminary selection of grains and drying and partial storage facilities are urgently needed. It is suggested that research and development of complete sets of food grains processing facilities (including dryers) by state-run farms be included as a key national project.

It was the view of the meeting that the small flat-bed type dryer, the simple storage type dryer and the fluidized-bed type dryer should be the main models for popularization. Rich communes and brigades can gradually popularize some cyclic type dryers that are structurally advanced and that have a better performance.

As regards the problem of energy for drying, the meeting considered that the state should appropriately provide oil fuel for commercial food grain bases and seed supply stations to guard against disasters and protect food grains, assure bumper yields and bumper harvest. In the broad number of villages, coal should be the main source of energy at present, and measures should be suited to local circumstances to develop dryers that use solar energy, small hydroelectric power, marsh gas and residual grain materials such as stalks and husks as fuel. The localities have commented that the supply channel for energy needed for drying at present is blocked and that concerned departments should urgently study the problem and solve it.

At the meeting, many beneficial opinions and suggestions were offered to hasten future development of the grain drying machinery industry in our nation.

NEW PROBLEMS FACING PRODUCTION RESPONSIBILITY SYSTEM NOTED

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] in Chinese No 3, 1982
pp 15-16

[Article by Shi Ronghua [4258 2837 5428], secretary of Rangyang County CCP Committee, Hubei Province: "Give Attention to the Study and Solution of New Problems in Production Responsibility Systems"]

[Text] Right now communes and production brigades are discussing and setting up 1982 production responsibility systems and signing contracts. All levels of leadership cadres should probe the realities and give attention to the study and solution of new problems regarding responsibility systems.

1. Production levels must not be set too low. The level at which production standards are set not only bears on the amount of real benefits the masses receive, but also has ramifications for the welfare of the state and the collective. Guided by "the principle that the masses should be allowed to exceed production when setting output quotas," some production quotas set by production team candres are not only lower than output during the past several years, but even state quotas cannot be fulfilled. Though accounting is done in some cases on the basis of average output for the last 3 years, since 2 of the past 3 years were years of diministed output, the production levels set are still less than for normal year harvests. In some cases, last year's actual output exceeded the originally prescribed output, but disasters were offered as an excuse for a general decline in output. In some places a situation has cropped up in which "anything more belongs to oneself with no fulfillment of state quotas and with nothing for the collective." Just where should output be set? First of all, we must rectify our thinking, define what it is that arouses enthusiasm, rely on policies confidently, and allow the masses to have genuine economic benefits. But one positively cannot suppose that allowing commune members to exceed quotas by a large amount is the only way that their enthusiasm will be great, that if they overfulfill quotas by just a little that their enthusiasm will be small, or that if they do not overfulfill them at all they will have no enthusiasm. Standards for setting output must be based on comparison with increases in output during normal years, and have as a prerequisite assured fulfillment and overfulfillment of state quotas if the enthusiasm of the masses is to be genuinely aroused, production potential tapped, a great contribution made to the state, and commune members are to be able to exceed output quotas.

2. Grain provided by the state at parity price must not be consumed while farm products are sold at high prices. This problem is a relatively conspicious one in places where land is scarce relative to the work force and where grain output has fallen as a result of disasters. With the establishment of responsibility systems linked to output, farm products are in the hands of commune members. In addition, under prevailing policies there are two markets and several prices for these goods. So, some commune members take farm products to markets or outside their locale to sell them for high prices, while state procurement quotas remain unfulfilled. Second, some commune members do not plant according to plan. They expand the growing of economic crops and cut back on the grain growing area, so grain procurement quotas are not fulfilled and the state is relied on to provide grain for consumption. Moreover, when quotas originally set for economic crops are small and actual output large, they sell a large portion in the market, keeping the money obtained for themselves. In addition to readjusting policies and making regulations more restrictive to counter this problem, cadres and the masses must be indoctrinated in establishing a patriotic sense and properly handling the relationship among the state, the collective, and the individual regarding benefits.

3. Procurement quotas must not be set for major farm products alone. As a result of the establishment of production responsibility systems, new changes have taken place in state purchase quotas. Formerly, for example, all quotas were set for production teams, but now product procurement quotas are levied on households. Formerly, grain and edible oil quotas stipulated only the quantity, with no breakdown by variety. Formerly there were only quotas for grain, cotton, and edible oil, and not for other economic crops. Consequently, all quotas must be readjusted and made specific. Unless this is done, problems will occur. For example, if there is only a general quota for grain while soybeans and mung beans command a high price in the market, some households will not sell soybeans or mung beans to the state but rather will fill their quotas with coarse food grains [e.g. corn, sorghum, and millet]. They will satisfy edible oil quotas by supplying rapeseed oil and cottonseed oil while keeping sesame oil for their own consumption or for sale at a high price. Once grain, cotton, and edible oil quotas have been fulfilled, items such as tobacco and peanuts, for which there are no quotas, will be sold at high prices. Therefore, to assure planting in accordance with state plans, all types of farm products should not only be assigned a procurement quota, but fixed quantity quotas for procurement at negotiated prices should also be set. Not only should quotas be placed on production teams but also on households. Not only should quotas assigned commune members by production teams be assured of fulfillment, but also overfulfillment by specific amounts, and contracts should be signed.

4. There must not be one-sided emphasis on letting commune members derive more real benefits and an abandonment of collective welfare endeavors. Following the establishment of production responsibility systems, in some places a situation has arisen in which "everyone did his own thing," and the collective was left without either money or grain. In many brigades, cooperative medical clinics closed their doors for lack of money to support them, and commune members went to hospitals to have their illnesses tended to.

Hardships difficult of solution occurred for the households enjoying the five guarantees and for hardship households. There was no grain or allowances for those who carried out construction, so it was difficult to find workers to send to perform tasks. Consequently, after establishing systems of responsibility linked to output, there must be no "dividing up until everything is gone or eating until everything is gone." The collective must withhold a certain proportion of public welfare funds in order to improve the material and cultural life of the people and to improve health standards.

5. There must be no linking of output to land or disbandment of collective industrial sideline occupations. Before the establishment of responsibility systems, many production teams had industrial sideline occupations, but following the establishment of responsibility systems for agricultural production, many production teams had no means of engaging in industrial sideline occupations for the following reasons: 1) management levels were low and income from some sideline occupations small, so they simply stopped working; 2) soil cutput was set too low, permitting production in excess of quotas, while sideline occupations provided no assurance of increased earnings, so those engaged in sideline occupations simply quit; 3) it was mistakenly believed that linking income to production meant a division of the fields for working individually and it was feared that no land would be available in future for those engaged in sideline occupations; 4) in places with little land relative to the work force, some commune members spent time on sideline occupations for which they were not accountable, pocketing the money they earned; in consequence, many of the processing plants, transportation teams, construction teams, carpentry teams, plaiting teams, hog raising teams, beekeeping teams, and such sideline occupations that the collective had formerly organized had no one to work them, and collective income greatly decreased as a result. In light of these attitudes and realities, policies must be made clear to cadres and the masses. Where management is poor, it must be strengthened. Where occupations can be carried on jointly by the collective and individuals, the collective and individuals should work together. For both agriculture and sideline occupations, output quotas should be equitably fixed and remuneration should be generally balanced. Specialized teams and specialized households can be established for industrial sideline occupations. In summary, where conditions permit, not only should collective industrial sideline occupations be consolidated but they should be steadily developed in order to find opportunities for surplus rural labor and to increase earnings for the collective.

RESULTS OF SCIENTIFIC FARMING EXPERIMENTS IN FIVE COUNTIES REPORTED

Beijing NONGYE JINGJI WENTI in Chinese No 2, 1982 pp 35-37

[Article by Chen Lin [7115 2621], Hao Qi [6787 3825], and Xu Xin [6079 6580], Agricultural Modernization Research Committee, Chinese Academy of Sciences, "How Five Agricultural Modernization Bases Launched Scientific Experiments"]

The Chinese Academy of Sciences and provinces concerned established at Taoyuan, Luancheng, Hailun, Yanchi, and Guyuan five agricultural modernization comprehensive research base counties for research and applied science and technology to hasten development of agricultural production. A brief summary of several understandings gained from the conduct of scientific experiments during the past several years are provided below.

Beginning With Reform of the Crop Growing System For Gradual Revival and Building of an Equitable Agricultural Ecological System.

In the several base counties as in the country at large, a single product economy over a long period of time has greated proportional imbalance in the internal structure of agriculture; the ecology has lost its equilibrium; and agricultural production has developed slowly. Changing this state of affairs to convert the vicious cycle in agriculture into a benevolent cycle requires a process and performance of a large amount of research.

By way of solving this problem, several base counties began with readjustment of crop patterns and restructuring of the farming system. For example in Hailun County from south to north there is an accumulated temperature difference of almost 300°C and a more than 100 millimeter difference in quantity of rainfall, so they readjusted crop patterns on the basis of accumulated temperature and accumulated water belts. In the north and northeastern areas, rainfall is fairly great and soil moisture conditions are rather good. The frost-free period is comparatively short too, so these areas were designated bean and wheat producing areas. Southern and southwestern portions where, spring drought occurs in many years and where accumulated temperatures are high were designated corn growing areas. In 1979 when only a portion of the corn growing area of the northeast was transferred to the southwest, and when only a portion of the wheat and bean growing area was transferred from the southwest to the northeast, grain yields increased by 14 million jin.

Taoyuan County is a transitional region between the central semi-tropical belt and the southern semi-tropical belt where natural conditions are complex. Formerly two crops of rice were promoted here with "arbitrary uniformity" in contravention of objective laws. This artifically intensified the labor shortage for the "three summer jobs" [planting, harvesting, and field care], and a large part of the workforce was shackled to paddyfields that accounted for only about 10 percent of the county's fields. The abundant natural resources could not achieve development and utilization, and for a long period of time no development of economic diversification could begin. The Changsha Agricultural Modernization Institute converted to the growing of a single rice crop one-third of the Guanshanling Brigade's wetlands that should not grow two rice crops. This emancipated workforces, changing the ratio of the workforce engaged in agriculture and in economic diversification from 8:2 to 5:5, economic diversification thereby attaining rapid development. The result of the experiment was that grain output increased 16.8 percent; costs dropped 13.8 percent; and average per capita income increased by 33.30 yuan. The results of their research spread without having been given any publicity, and by 1981 77 production brigades followed them to do the same thing.

Through the introduction of early ripening fine corn variety, "Jingzao No 7," Luancheng County aslo solved problems with machine planting. A farming system of flat seeding [as opposed to sowing in raised rows or beds] of wheat and corn as two separate crops was universally promoted in production. In 1980, despite severe disasters, yields rose from 300 to 400 jin in ordinary years to 614 jin per mu, a 21 percent yield increase. This reversed a situation that had endured for many years of "summer high and autumn low." During the past year or two, intercropping of corn with pulse crops has further improved this farming system.

In restructuring the farming system and readjusting crop patterns in order to establish an equitable agricultural ecological system, the vicious cycle in agriculture thereby becoming a benevolent cycle, these three base counties have taken a heartening step.

While studying and restructuring the farming system, the three base counties of Hailun, Taoyuan, and Luancheng selected a number of production brigades for study of the optimum structural proportions of farming, forestry, livestock raising, sideline occupations, and fisheries in terms of distribution of workforces, rational utilization of resources, transformation of energy and resources, and increasing earnings from sideline occupations. For many years Taoyuan County has used rice straw for livestock feed. While studying the benevolent cycle system in large scale agriculture, fields dependent on rainfall and where harvests are very low) were converted to the growing of hybrid corn. Test planting of a single crop of early corn on these lands in 1980 produced yields of about 600 jin per mu. In 1981, late crop corn yields amounted to from 300 to 400 jin per mu or almost 1,000 jin for two crops. This was between one and two times as much as from the growing of paddy rice. Use of fields dependent on rainfall for the growing of corn not only solved the problem of fodder for poultry and livestock, but also solved the contradiction of competition for water between paddyfields and ponds.

The Hubei Aquatic Products Institute conducted experiments with the raising of fish in paddyfields at Taoyuan. They used a method of digging pits in paddyfields to solve contradictions between shallow watering, frequent watering, sunning the fields, and the raising of fish, obtaining very good results. Net income per mu from fry was about 15 yuan. After fish were raised in the paddyfields, virtually all of the weeds in the fields were eaten by the small fish; major soil nutriments increased; and paddy yields increased 15 percent. Net income from fields in which fry were raised increased 46 percent. Taoyuan is preparing further to combine paddyfield and pond raising of fish, and reservoir and river raising of fish, to form a freshwater breeding system.

These experiments brought about changes in the existing structure and performance of the ecological system, accelerated the material cycle, and heightened the energy transformation rate.

Attention to Key Techniques and Organization of Comprehensive Scientific Experiments

Limiting factors impairing production existed in the agricultural production of all base counties. In Taoyuan County, for example, the protracted drowning of paddyfields has given rise to secondary gleying of the soil. The gleying area accounts for about 40 percent of the paddyfield area. In the management of its crops, Luancheng County has violated objective laws using large amounts of water, fertilizer and seeds so that output is not worth the costs, production expenses per mu amounting to 40 percent or more. In Yanchi County quality of flatland sheep had dropped and the rate of removal from inventory was low. In focusing on these problems, many specialities and many disciplines were organized for comprehensive experiments and large scale cooperation that transcended departments. Results of research on individual facets was organized into a coherent whole and converted into techniques that could be applied. This produced outstanding results and greatly accelerated the process of converting research results into productivity. For example, application of a number of principles and methods of genetics to figure out the interrelationship between the number of twists in flatland sheep wool spikelets and other properties and generic capabilities in order to set criteria for breeding of fine varieties and selecting the finest of the fine, thereby rapidly upgrading the inherent fine traits of flatland sheep. Production units set up an associated artificial insemination station, which increased the breeding rate for rams from the natural breeding rate of five to 10 to more than 200 ewes. At the same time they vigorously culled out rams, weak sheep, and inferior sheep from the flocks, the structure of the flocks becoming more rational thereby. Within a period of 2 years, the size of flocks has increased eight percent, and income from livestock products has increased 61 percent. No more than 2 to 3 years were required from research to application to production. Such speed is rare in agricultural research.

Taoyuan County's experiments with changing the secondary gleying of paddyfields was done by improving paddyfield water conservancy facilities, rotating between wetland and dryland crops, lowering the ground water table, improving the physical and chemical structure of the soil, and decreasing toxic reduction materials. After the soil had been improved, springtime mud temperatures rose to 1 to 2°C, and injurious reduction materials declined; effective potassium increased 0.5 mg/100 grams of soil; effective phosphorous increased by 0.69 mg/100 grams of soil, and soil pH rose from 4.32 to 5.61. In the same year paddy yields increased by 100 to 200 jin per mu.

As the role of science and technology in economic construction continuously expended, developmental research to promote new techniques and new materials received serious attention universally within the country. Development research is a bridge whereby science and technology is transformed into productivity to become more important in agriculture. This is for the following reasons:

First, results of agricultural research, and particularly results of individual technologies are obtained in the non-productive conditions of laboratories or small area experiments. Their application to production will additionally require a research process whereby they are paired with and adapted to other technologies.

Second, before research results can be applied to production, intermediate experiments are performed in industry while this stage is a void in agriculture.

Agricultural modernization experimental basis can use the method of "take-ism," comprehensively applying existing research results to launch research to fill in gaps to complete a chain, using it as one's own point of departure for research. First comes copying, followed by innovation with innovation coming in the course of use, and technical and theoretical development taking place on a higher plain from a foundation of solving real problems in production.

Use of Technology Requiring Small Investment That Shows Quick Results and Great Benefits With Research Placed in an Important Position

Judging research results requires, first of all, a look at its direct economic benefits for production or its anticipated results in spurring economic development. Because China's agricultural techniques and equipment are relatively poor, and peasant cultural levels and knowledge of science and technology relatively low, in order to realize increased output over large areas technology that requires little investment, brings quick results, and is simple and readily usable is all the more necessary. In our experiments at base counties, this kind of research was put in a priority position.

Yanchi and Guyuan counties are windblown and arid areas where evaporation exceeds rainfall, water becoming a limiting factor on agricultural development. For these counties to resort to construction of water conservancy as other places do to solve the problem of irrigating fields is clearly difficult. Consequently, how to conserve natural rainfall becomes a major research problem. The Desert Institute of the Chinese Academy of Sciences worked from analysis and mystery of the laws governing local rainfall and their relationship to crop growth and development. Before the advent of the rainy season, they loosened the soil deeply but did no further plowing of it. This is called the deep loosening method or little cultivation method, and, as compared with traditional farming methods, it greatly increases soil capacity to take in and store moisture. Between 0 and 50 centimeters down, soil water content is increased 13.2 percent between 30 and 50 centimeters water content is increased 47.7 percent. Broom millet output increased 13.4 percent, and millet output increased 31.9 percent. Since this method does not disturb the surface horizon of the soil, a substantial amount of crop stalks and other leavings can be retained; these reduce soil evaporation and erosion. Since this technique is uncomplicated and easy to apply, while the experiments were going on nearby peasants wanted to use it. Decision has been made to promote throughout the county the large numbers of armless, deep-loosening farm implements produced by the Yanchi County Farm Implements Plant. Though results of research of this kinds have extremely evident economic benefits, some people feel they do not reflect scientific "refinement " These people do not realize that sucn methods can increase production and are welcomed by the masses.

Luanchen County was a famed cotton producing county before Liberation, but in view of the emphasis given to "early" in the farming season during the past 10 years or more, disease has been serious during the seedling stage, plants have been missing and the soil cracked around plants. Yields fell to 20 or 30 jin per mu. Research has shown that a 15 to 20 day delay in the time of sowing, in accordance with different temperature requirements for cotton seed sprouting and elongation of embryo stems, brought full stands of plants and sturdy stems, providing a fine basis for the 80 jin per mu cotton yields for the county as a whole in 1981.

Fine varieties are also technical measures in the category of requiring little investment, bringing quick results, and providing great benefits. Several base counties rather diligently set about purification and rejuvenation of varieties, and perfected fine variety propagation systems from which results have begun to be obtained. Nevertheless, the potential has not yet been very well exploited, and work requires further strengthening.

The aforementioned research work has not been seriously viewed for a long time, and at times it has been derided as the work of "evil people." The researchers engaged in this kind of research work received no support or were even looked down upon. I feel this situation is related to the country's policies toward science. Formerly we evaluated and rewarded research results in terms of "use." Therefore, henceforth we should change this state of affairs through policies toward science and management of research so that science and technology will play a role in the advancement of agricultural production.

Development of Industry That Can Be Used By Agriculture Locally to Solve the Problems of Technical Change of Matters in Nature

Quite a few research results need to be turned into products or necessary material conditions for their application provided before they can be applied to production. This is because research results generally are things that belong to the category of an intellectual formulation that cannot be directly applied to production. An example is full rate livestock feed and compound fertilizer, the nutrients in which are abundant, which are proportionally balanced, are of high efficiency, and which have been generally applied abroad with success. In recent years research in their use in some parts of China has brought fine results. However, unless a modern livestock feed and compound fertilizer industry is built, and problems in the socialization of the supply of products solved, advanced technology cannot be translated into productivity.

Solution to problems of technical change of matters in nature and development of agricultural industries requires overall planning by the state. Insofar as its strength allowed, Luanchen County established livestock feed processing plants and studied three formulas for production of hog feed. After these feeds were used the pork to feed ratio declined from 1:5-6 to 1:3.8, the return on feed increasing by 30 percent or more.

The Ministry of Chemical Industries conducted compound fertilizer experiments at Luancheng and prepared to convert small chemical fertilizer plants to compound fertilizer plants. At first they experimented with compound nitrogenous and phosphate fertilizer gaining yield increases of about 15 percent as compared with use of the same quantity of nitrogenous or phosphate fertilizer.

During the past 3 years, several base counties have launched experiments in the application of the results of a hundred or so large and small research projects, all of which have resulted in yield increases to varying degrees. However, some results have been taken up for use and others have not. The reasons for this, apart from inadequacies in the techniques themselves, that they are not key measures for increasing yields, and that the masses find them a bother to use, lies in problems the technical change of substance. Therefore, development of agricultural industries and building of a modern industrial base to render service to agriculture are indispensable material conditions for hastening the application to production of the results of scientific research.

USE OF PLASTIC SHEET MULCHING FOR UPLAND RICE EXPLAINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 8 Apr 82 p 4

[Article by Yi Cai [2496 2088] : "Plastic Sheet Mulching for the Growing of Upland Rice"]

[Text] In North China water resources are limited, to the detriment of paddy rice production. The use of plastic sheet mulching to grow upland rice is a new means of saving water in growing rice. Experience has shown the actual need for water of paddy rice to be somewhat less than for upland rice. Paddy rice can grow normally in a comparatively fertile cultivated layer using plastic sheet mulching where the soil water content is around 20 percent. Once the plastic sheet has been put down, water in a deep layer of soil has a tendency to move toward the surface layer. This is because moisture evaporated by the sun's rays condenses when it hits the plastic and forms droplets that drip onto the surface of the soil. Plastic sheet mulching also raises the soil temperature. The increase in temperature during May and June is particularly apparent. At a depth of 5 to 10 centimeters in the cultivated layer, the average daily temperature increase is between 1.2 and 3.6 degrees centigrade. Under conditions of high temperature and great humidity, microorganism activity increases, thus promoting the breakdown of soil nutrients, improving the physical properties of the soil in the cultivated layer, and creating a favorable environment for early stage rice growth and development.

When plastic sheet mulching is used for upland rice, either dry seeds may be dibbled into holes or seedlings may be grown for transplanting. Practice has shown that it is easier to get full and even stands of rice from the transplanting of upland propagated rice than from the dibbling of dry seeds, and elimination of weeds during the early stage is also helped. Usually 0.015 millimeter think transparent plastic sheeting is used as a mulch; holes are punched in it to suit rice planting density, the best hole size being 4 centimeters.

For growing upland rice using plastic sheet mulching, insofar as possible, low-lying easily flooded waterlogged land and flatland that can be easily soaked where wetland and dryland intersect should be selected. Results in the growing of rice using plastic sheet mulching are best in places that are dry in early spring, where water is lacking for the transplanting of rice seedlings, where the land is prone to waterlogging during the rainy season, and where yields from dryland crops cannot be assured. Fields having overly small amounts of rainfall must have irrigation facilities in order to provide "life-saving water" when needed.

For upland sowing, varieties must be selected that are drought-tolerant, short-stemmed, disease-resistant, lodging-resistant, early maturing, and high yielding. In propagating seedlings for transplanting, local intermediate ripening varieties should be selected. Because rice development is restricted by a shortage of water, ripening will occur later than when grown in paddy fields.

Once the mulch sheet has been put down, it cannot be removed for weeding; therefore, a herbicide should be used to get rid of weeds before the plastic is laid. Between 6 and 8 liang of 50 percent benthiocard of 40 percent nitrofen per mu will effectively eliminate weeds and will be relatively safe for the rice. Herbicide strength must be accurate and spraying must be done evenly. Miaoyan weeds [5379 4190 5430] have to be removed by hand or cleared away with herbicide.

The land must be turned well and raked finely. All stubble and weeds must be cleared away entirely, and the surface of fields or mounds where crops have grown must be rolled flat. The plastic sheeting must be stretched taut, laid flat, and it must hug the surface of the ground; soil must be placed on its edges to hold it down so that the wind cannot lift it and allow soil moisture to escape.

Plants should be 3 cun apart, about 20,000 holes per mu being planted. Six or seven plants should be transplanted into each hole or 10 to 12 seeds planted per hole so as to get about 15 panicles per hole.

For fertilizers, farmyard manure and sufficient phosphate and potash fertilizer should be used, the amount of nitrogenous fertilizer being reduced to about one-third the amount usually used on paddy fields. This fertilizer should be applied over the entire field and worked into the soil before sowing. If fertilizer appears lacking in the later stages, fertilization for heading or grain formation may be carried out. Fertilizer can be applied before rains, or the plastic may be broken and fertilizer dibbled in, or leaf surfaces may be sprayed with fertilizer.

Plowing and ridging should be carried out in early spring to prepare the field plots and advantage should be taken of soil moisture to sow or transplant early. Places having experience in seedling propagation might best propagate sturdy upland seedlings and plant them early at the right time. Where soil moisture conditions are fairly good, survival is possible without flooding the fields, but transplanting should be carried out quickly right after rains. In both early sowing and early transplanting, soil should be used to close planting holes tightly.

NECESSITY FOR MULTIFORMITY OF RESPONSIBILITY SYSTEM EXPLAINED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese
No 2, 1982 pp 8-13

[Article by Yu Feng [5713 6912] and Chen Wenke [7115 2429 4430] of the Hubei Social Sciences Institute: "A Trial Discussion of the Multiformity of Our Country's Agricultural Production Responsibility System in the Present Stage"]

[Text] Over the past 2 years, various forms of the agricultural production responsibility system, characterized by linking remuneration to output, have been further developed in the vast rural areas of our country. Their speed of development and proliferation have already greatly exceeded people's expectations. People had originally envisaged that three forms of the responsibility system--contracting production to households, assigning output quotas to individual able-bodied laborers, and specialized contracts that link remuneration to output--would respectively suit our country's poor and backward areas, intermediate areas, and advanced areas. However, as things developed in practice, the household contract form developed in the communes and production teams in some advanced areas, while in some poor and backward areas the output remuneration form is vigorously practiced, and even within the same area where the levels of productive force are for the most part identical, the production responsibility system has become the antithesis to the past form of agricultural management and administrative known as "one knife for everything," i.e., rigid uniformity. The production responsibility system is suited to our country's multilevel agricultural productive force as well as to its multilevel management and administration. Its emergence and development was an objective necessity.

I. The Multilevel Nature of the Productive Forces Determines the Multiformity of the Responsibility System

Since the beginning of the construction of socialist collective agriculture in our country, production conditions have markedly improved and the production level has been greatly raised--this must be fully affirmed.

1. The degree of simplicity and complexity of production tools varies, as does the level of agricultural machinery. Some production is modernized, mechanized large-scale production, like some people's communes in the suburbs of a small number of large cities; some production is semimechanized, semimanual labor

production, like many communes and production teams in areas such as the southern plain of Jiangsu Province; and some production is completely manual labor production, and there even is still the primitive, backward slash-and-burn cultivation.

2. The cultural levels and the scientific and technological levels of the laborers, as well as their technical ability in production, vary. In some places where elementary school education and junior middle school education are universal, the commune members' level of scientific farming is fairly high, they can fairly well master and use new agricultural technology, and they are good at working on sideline occupations and running a diversified economy. In some places where the majority of the peasants have an educational level of lower primary school and above, but a minority of them are illiterate or semi-illiterate the raising of their level of scientific farming is not fast, their study and mastery of new technology is also limited; and there are still many places where educated people are in the minority and there is a lack of agro-technical talent, which seriously affects the raising of the level of scientific farming and the spread and use of new technology.

3. The labor objectives (including cultivated land, water areas, mountain forests, etc) are intrinsicly different and the degree of their exploitation and utilization are different, so the patterns and methods of production are also different. Take cultivated land for example. Not only are plains and lakeside areas different from hills and mountain areas, but the former is concentrated linked strips of land convenient for mechanized work and collective labor, while the latter is fragmentary, scattered pieces of land inconvenient for mechanized work and collective labor; and within plains and lakeside areas, becuase water power conditions and technical equipment will be different, the degree of the exploitation and utilization of cultivated land will also be different. In some places there will be gravity irrigation or electromechanical irrigation so that all the fields will timely be put under water to protect the harvest, and in still other places the peasants "depend on heaven for their food."

4. The degree of socialization and specialization of production varies. In some places the level of socialized production is quite high and there is a clear division of work and operations, and there has been initially formed a rural economic structure in which agriculture, forestry, animal husbandry, sideline occupations, and fishery are comprehensively developed and in which agriculture, industry, and commerce are comprehensively managed; in some places although the enterprises run by communes and production teams and the diversified economy have been developed, the specialized division of work is not clear and the relations between various departments and various trades are not very close; and in still other places single-crop planning is practiced, socialization and specialization of production is out of the question, the great majority of farmwork is suited to the work of individual laborers, with each household able to finish the entire process of crop production from sowing to harvesting, and thus between the laborers there are still simple work relations.

Since the agricultural productive forms are in this state of being multilevel and unevenly developed, the agricultural production responsibility system, which is a form of administering and managing a socialized, collective agriculture, must be adapted to these circumstances and take on multiple forms and cannot take as its model the past practice of "one knife for everything." For example, in the place where the three provinces of Hubei, Henan, and Anhui meet, the principal form of the responsibility system practiced by each province form of the responsibility system practiced by each province is different: The Zhangguanghe Commune in Macheng County, Hubei, practices the multiform responsibility system with emphasis on specialized contracts linking remuneration to output; and Henan and Anhui practice the multiform responsibility system with emphasis respectively on assigning output quotas to individual able-bodied laborers and on fixing output quotas based on households which assume full responsibility for task completion. Why is it that, in the same mountainous area where production conditions are approximately the same, the forms of the responsibility system practiced are different? This is because in Zhangguanghe Commune, Macheng County, the development of forestry and other parts of its diversified economy is faster than that of the communes in the neighboring provinces and is at a certain level of specialized production. Not only is this the case in one province, one county, or one commune, but it is also the case in one production brigade or one production team. In the No 8 Team of the Shafan Production Brigade, Huilong Commune, Huanggang County, Hubei, households are small and machines few, so agricultural production depends on the labor of men and animals. Proceeding from the local situation in agriculture production, and according to the different crop situations, they have carried out the multiform responsibility system with emphasis on assigning output quotas for field crops to individual able-bodied laborers: 1) for the summer grain crop (wheat), the form of contracting a job to be done in a certain period of time and of managing by quotas is practiced; for the summer oil crop (rapeseed), the form of 1 person per 1 fen of "edible oil plots" is practiced, i.e., every person tills 1 fen of rapeseed land for which he pays 1.5 yuan of land cost and receives 5 jin of edible oil; 3) for early and late paddy rich on large plots close at hand, the form of assigning output quotas to individual able-bodied laborers is practiced; 4) for early and late paddy rice on small plots far away, the form of contracting production to households is practiced; 5) for cotton, the form of 4 li [1 li = 0.666 square meters] of land per person with the person paying 1 yuan in land cost and retaining for himself 2 jin of cotton is practiced; and 6) with the exception of planted cotton, for 1 mu of dry land and several dozens of paths between fields, the form of contracting production to households, with full awards and compensation, is practiced. Looking at this situation in Huilong Commune, where this team is, and at the situation in Huanggang County, the forms of the multiform responsibility system that are primary are the assigning of output quotas to individual able-bodied laborers and the specialized contracting that links remuneration to output, and there are extremely few teams that practice the forms of quota management and household contract production. If one were to rigidly make this team the model for the whole commune and even the whole county, this would obviously be unworkable. Because in this team the level of mechanized work is low and the fields are relatively scattered, and within the whole commune and the whole country, the level of production forces is fairly high and different levels are formed, and so the forms of the responsibility system are not all identical.

From this one can see that the multilevel development of the productive forces, especially the level of production tools and technical equipmemt, plays the decisive role in the emergence and development of the different forms of the responsibility system. The productive forces determine the production relations, which mainly means that the forms of the means of labor such as production tools determine the forms of the ownership system and that the level of the technical equipment composed of the means of labor such as production tools determine the form of the organization and management of labor. Just as Marx expounded many times: "The means of production determine the labor organization." ("Complete Works of Marx and Engels," vol 31, p 236) "For the composition and division of labor, we look at the tools possessed for it and their differences. The division of labor determined by manual grinding is different from the division of labor determined by steam-power grinding." ("Complete Works of Marx and Engels," vol 4, p 163)

Of course, it is correct for many articles to cite the abovementioned expositions by Marx when stressing that with the difference in production tools the specific forms of the responsibility system are also not identical. However, we cannot make the decisive role of the difference in production tools absolute, and prove merely from the different levels of the production tools that the emergence of various forms of the responsibility system is an inevitability. Seemingly, the more advanced the production tools the greater the scale of the labor organization, and one can only practice a form of the responsibility system in which there are relatively many components of unified management and administration (like the specialized contracts linking remuneration to output). Conversely, if the production tools are backward the scale of the labor organization will be small, and one can only practice a form of the responsibility system in which the components of unified management and administration are few (like large-scale assignment of responsibilities). This conclusion is open to question. First, the emergence of many forms of labor organizations and of many forms of the responsibility system was the result of many factors and multiple effects. It is true the level of development of the productive forces is a factor that plays a decisive role, but the multilevel productive forces are not to be completely equated with the multilevel production tools. Looking at history we see changing factors affecting production relations (including the forms of management and administration), and these factors are certainly not merely the production tools. Take manual tools for example. Manual tools are used in small-scale production, as they also are in the initial stage of capitalism. The high-level agricultural producers' cooperatives set up in our country after the cooperative transformation of agriculture also used a large amount of manual tools. Next, that the production tools determine the composition and division of the labor organizations does not mean that the level of production is in direct ratio to the size of the labor organization or the number of unified management and administrative components in the responsibility system. Practice proves that following the raising of the level of production tools, the scale of a labor organization can either expand or contract. We must now focus on the following situation that people overlook.

II. The Multipliformity of the Responsibility System Is Suited to the Level of Multilevel Management

As we stated above, the agriculture production responsibility system with its many forms was the result of many factors and multiple effects. We hold that, in addition to the chief determining factor of the level of development of the productive forces, the other factors should include: the size of the production team, the degree of concentration and dispersion of where the commune members dwell, the laborer's understanding and desires, the level of the cadres' experience and management, etc.

Among them, the level of management and administration is a factor second only in importance to the level of the productive forces. The form of the agricultural responsibility system must be suited to the level of management and administration.

At the present stage in our country, the situation of management and administration in collective agriculture, like the situation in agriculture production, is at a level of development that is uneven and itself multilevel. 1. Looking at the methods of management and administration, we see that, owing to the differences in production tools and technical equipment and to the difference in the scale of production and the degree of production socialization, some methods are suitable for unified management and administration of a collective (like for large farm implements, large and medium-sized water conservancy installations, or enterprises, run by communes or production teams), some methods are suitable for dispersed management and administration (like for small farm implements and small water conservancy installations), and still other methods are suitable for separate household management and administration; some methods are suitable for the practice of the collective responsibility system, some methods are suitable for the practice of the individual responsibility system, and still other methods are suitable for the practice of a combined collective and individual responsibility system. 2. Looking at the capabilities of managers and administrators, we see that, owing to their different levels of education and technology and their different amounts of experience, there are fairly large disparities manifested in management. Some managers and administrators have a certain amount of scientific and technical knowledge and rich practical experience, so that they truly know the ins and outs of their tasks and can manage fairly well the plans, labor force, property, and materials of the people's commune as the basic accounting unit. And there are also some who are fairly lacking in educational knowledge and practical experience and who basically do not know the ins and outs of their managerial and administrative tasks, and thus their management and administration are in a state of confusion. 3. Looking at the characteristics of our country's agricultural production at present, we see that, owing to the fact that in many places the levels of mechanization, water conservation, and technology are fairly low, we must, proceeding from the actual circumstances in which agricultural production has a dispersed nature, seasonal nature, and cyclical length, adopt different labor combinations and management forms. For some characteristics suitable for centralized labor, unified management is practiced. For some characteristics suitable for dispersed labor, a combination of unified management and division work responsibility is practiced. For some characteristics suitable for individual labor, the individual responsibility system under unified management is practiced. Therefore, no matter whether we proceed from the multilevel productive forces or from the multilevel management and administration, under the premise of upholding the socialist ownership system with the rural people's commune as the basic accounting unit, we must practice many forms of management and administration, including forms of the responsibility system, and we must not rigidly adhere to one centralized, unified form, in order to even better improve the people's relations of cooperation in the course of production, promote the further integration of the laborer with the means of production, and to the greatest extent possible display the superiority of the socialist collective economy and arouse the production enthusiasm of the individual member.

As early as 20 years ago, Comrade Chen Yun pointed out: Under the guidance of state plans, there should be a diversity of forms in management and administration. He said: "We must correct in good time the mistaken course of action in which attention is paid only to centralized production and centralized management, and in which dispersed production and dispersed management is neglected." However, since 1958, what has mainly been practiced in our country's collective leadership is a highly centralized form of administrative management. It is prominently manifested in two aspects: First, the commune, the production brigade and even high-level departments practice highly centralized, unified administrative management over the production team. The commune and the production brigade represent the state's political power and issue mandatory plans to the production team, and impose equaliterian and indiscriminate transfer of the manpower, material resources, and funds of the production team. The production team is the purely economic organization of the kind there was in the period of cooperativization. Second, the production team also exercises highly centralized, unified administrative management over the commune members. The cadres of the production team not only control and manage the whole production of the team, including the planning, management, and harvesting of crops and the team's industrial and sideline production, but also control and manage the management and administrative measures for production and the distribution of income, down to that of the household sideline occupations of commune members. From looking at the above two aspects, we see that not only does this centralized, unified pattern of administrative management limit, with regard to system, the right of production teams and commune members to make their own decisions, but also the work involved in this kind of complicated centralized, unified management makes it hard for the cadres of communes and production teams, particularly the vast numbers of production team cadres, to be equal to their jobs. Precisely because the situation is like this, the great number of cadres and masses have all along demanded that this kind of single administrative management model, which is divorced from reality, be reformed and replaced by multiple forms of management and administration that are in accord with local natural conditions, economic conditions, and cadre management level. Stressing the significance of this, the emergence of multiple forms of the agricultural responsibility system over the past 2 years in our country is precisely a negation of the past pattern in our country of highly centralized and unified administrative management, and is also a product of the contradiction between the multilevel production, multilevel management and administration and the pattern of highly centralized and unified administrative management.

The new situation that has appeared in the development of the agricultural production responsibility system also proves: what kind of responsibility system a place practices cannot be divorced from the management and administrative level of that place. Generally speaking, in communes and production teams where the level of management and administration is high and the cadres' work style is also good, it is easy to practice unified management and the comparatively complicated form of the responsibility system represented by a method of output-linked remuneration (like specialized contracts); conversely, even if the level of productive forces is fairly high, more often than not we should choose unified management and the form of the responsibility system represented by a simple, convenient, and easy to carry out method of output-linked remuneration (like large-scale assignment of responsibilities to each household). In different areas where the level of productive forces is more or less the same, the effect of the level of management and administration on the choice and determination of the form of the responsibility system is even somewhat more obvious. We made a preliminary analysis of the situation of the agricultural production responsibility system in 10 countries of 4 prefectures (municipalities) in Hubei Province, and observed the following situation worthy of attention: 1. In counties and communes where the level of productive forces is comparatively high, because of problems concerning the management and administration level and the cadres' work style, the "double contract" form, i.e., fixing output quotas based on households and peasant households assuming full responsibility for task completion, of the responsibility system is practiced by a comparatively large number of production teams. 2. In counties and communes where the level of productive forces is fairly low, because the cadres possess a certain level of managerial and administrative expertise, the forms of the responsibility system practiced are specialized contracts and the assigning of output quotas to individual ablebodied laborers. 3. In counties and communes where the levels of the productive forces are more or less equal and the levels of management and administration are different, the main forms of the responsibility system practiced by each county and commune are not all the same.

To sum up, the conclusion is extremely clear: the many forms of the agricultural responsibility system are not only first decided by the level of the multilevel productive forces, but at the same time are decided by a given level of the productive forces being suited to the level of the multilevel management and administration. Admittedly, under given conditions the level of management and administration has a certain decisive effect on the form of the responsibility system, and is advantageous for correctly analyzing the conditions and reasons for the emergence and development in our country of the multiform agricultural responsibility system and for finding answers that conform to the actual situation.

As everybody knows, management mainly includes two aspects: 1) regulating the coordination between men and materials (the means of production), and organizing cooperation between man and man in the production process; and 2) regulating the relations between man and man, and managing the system and ideological-political work. We maintain that, with regard to these aspects, management should fall into the category of a productive force, and that not only does the combination of men and materials produce a productive force but also the cooperation of man and man in the production process forms a productive force, a kind of "collective force." In "Das Kapital," Marx many times employed the concept of "labor's social productive force" or "social labor's productive force," and what he was referring to was precisely the productive force produced from labor's social combinations, viz, coordination. Of course, in comparison with the ordinary meaning of productive force, the meaning of this productive force of management is relatively wide, and we can say it is a productive force in the broad sense of that term. In this sense, the decisive effect of the level of management and administration on the form of the responsibility system and the decisive effect of the level of the development of the productive force are identical. From looking at the course of development in both domestic and foreign agriculture, we see that the higher the degree of specialization and socialization in agricultural production, the greater the demand for scientific management and administration. This scientific management that we regard as a productive force, jsut like science and technology, not only has a great effect on the development of all the productive forces, but also directly affects the transformation of production relations. Therefore, in our current changing of the forms of rural management and administration and establishing of a multiform production responsibility system we cannot but pay attention to the important factor of the level of multilevel management in our country's socialized collective agriculture at the present stage.

III. Proceeding From Reality, Adhere to the Multiformity of the Responsibility System

According to the above analysis, proceeding from the level of productive forces as well as the level of the multilevel management in our country's collective agriculture, and under the premise of socialist public ownership of the means of production in our country's agriculture at the present stage, there should emerge a situation in which many forms of the responsibility system exist side by side, viz, both a collective responsibility system and an individual responsibility system; a lively situation which can both display the superiority of unified management of the socialist collective economy and also arouse the enthusiasm for production of the masses of peasants and individual peasants. Looking at the present time, if we are to do this, there are some theoretical and practical questions that must be studied and inquired into.

1. The question of the multiformity and multilevel nature of the responsibility system.

At present there is a relatively prevalent view, viz, the drawing up of specialized contracts linking remuneration to output is a high grade form of the responsibility system, the assigning of output quotas to individual able-bodied laborers is a middle-grade form of the responsibility system, and the "double contract" is a low-grade form of the responsibility system. We hold that the multiformity of the responsibility system is not to be equated with its multilevel nature. Although each form of the responsibility system has its advantages and disadvantages, and under different conditions the degree of advantage or disadvantage is also different for each form, it is difficult to say that the division of the forms into a number of grades is a scientific division. Marxism tells us that in a certain historical stage of society there is a certain production level suited to that stage and there can only be certain production relations, and in this there is no division into advanced and backward, high grade and low grade. The forms of the responsibility system fall within the category of production relations--without exception of course. Looking at the many forms of the responsibility system now practiced in our country, we see that no matter whether it is a form that is not a joint production form (like a contract for managing quotas and completing a job in a certain period of time) or a form of joint production, all of them have their own suitability.

If you want to rigidly differentiate what form is advanced, the criterion is suitability. Whatever form, at a given time and place suits the level of the productive forces and the level of management and administration, and is able to effectively arouse the enthusiasm of the great number of cadres and masses, is an advanced form; advanced and suitable are identical. For example, the form of the responsibility system in which there is a large-scale assignment of responsibilities not only is suited to the communes and production teams in some areas of our country where agricultural production is backward and the peasants have difficulties in their livelihood, but also has its suitability for some areas where the level of the productive forces is high or intermediate. It is a "form of the responsibility system universally suited to the entire country," but then how can we categorically assert that, based on certain of its limitations (like being small and complete), it is a low-grade form of the responsibility system suited to a low level of productive forces? Can we say that the so-called high-grade form of the responsibility system--specialized contracts--does not have a single drawback? Again, for example, we cannot rashly state categorically that the form of quota management and contracting a job to be done in a certain period of time is a low-grade, backward form; although it contains certain drawbacks in its method of management and remuneration, it also is not without its suitability. From the viewpoint of time, we see that, in the period of agricultural cooperativization and in the period following it, under conditions in which there were few items of production and the scale of management was small, this form emboided fairly well the system of distribution according to work and aroused the commune members' enthusiasm for production. Even now, some communes and production teams whose level of management is fairly high still successfully practice this form. From the view point of space, the fact that in the past in the greater part of the country this responsibility system was practiced, and that it is today still being practiced in a part of the country, shows that there is a rationality and progressive nature in its existence. Therefore, we must admit that the tendency in the agricultural economy is toward development of work division, coordination, specialization, and socialization. Based upon actual conditions, we can practice forms of the agricultural production responsibility system that are advantageous for specialization and socialization, but we cannot, separating ourselves from the level of the productive forces and the level of management and administration under certain historical conditions, divide the forms of the responsibility system into high grade and low grade, and abstractly talk about the advanced nature of the specialized contracts and the "backward" nature of the "double contract" and quota management forms. If we separate the forms from suitability and stress their advanced nature, we are bound to cause one-sidedness, do things poorly, and very possibly, consciously or unconsciously, return to the past practice of "one knife for everything" and the old path of having only one model. We must further study and comprehend this passage in the sixth plenary session's "Resolution on Certain Questions in the History of Our Party Since the Founding of the PRC": "The development of socialist production relations does not follow as one fixed model. Our task is, in line with the demands for development of the productive forces in our country, to create at every stage specific forms that are suitable for that stage and that make it easy to continue the advance."

2. The question of upholding the multiformity of the responsibility system under the principle of the socialist system of public ownership.

The premise for upholding the multiformity of the responsibility system is the socialist system of public ownership. A fundamental goal of our practicing the multiform responsibility system is to display to the greatest extent the superiority of the unified management of the socialist collective economy and to arouse to the fullest the enthusiasm for production of the individual commune members, so that the forms will organically combine to speed up the development of agricultural production and satisfy the people's daily increasing necessities of life. Viewing the present situation, there are two tendencies affecting the above-mentioned organic combination. One tendency is that the "leftist" pernicious influence is still making trouble, is still uniting and controlling too much, and no matter whether it is large or small farmwork, no matter whether it is sowing or harvesting, these ideas rise up and unite. This not only fetters the enthusiasm and creativity of commune members, but also, to a very large degree, obstructs the superiority of the unified management of the collective economy. The other tendency is to abandon leadership, holding that the joint production responsibility system must be mostly divided and little united, and even only divided and not united, so that the united is not united, so that, for example, the large and medium-sized farm implements, the water conservancy installations, the collective mountain forests and collective orchards, etc, all lack unified management. This way of one-sidedly stressing the strong points of dispersed management and individual administration overlooking the strong points of collective, unified management is disadvantageous to the display of the superiority of the collective economy, is disadvantageous to the rational use by the masses of commune members of machinery and water conservancy installations, to their effective utilization of various natural resources, and to their creation of even more financial resources. Therefore, if we want to maintain the position of the production team as the main part and give play to the combination of the superiority of the collective economy and the individual's enthuriasm, we must correctly handle the relationship between unity and division, uniting what is suitable to be united and dividing what is suitable to be divided. For the majority of areas in the country, the "unity" aspect should at least include unified plans, unified accounting, and unified deployment of manpower, and the "division" aspect should as far as possible take whatever items that can be managed and administered in a decentralized fashion and contract them out to manpower or commune member households. The specific conditions in various areas are different, and the degree and methods for unity and division are not of the problem of unity and division not only is an objective demand for further giving play to the superiority of the collective economy and to the enthusiasm for production on the part of individual commune members, but also is the key to whether the various forms of the responsibility system can develop healthily.

3. The question of the masses' desires and the choice of the various forms of the responsibility system.

In the majority of cases, whatever form of the responsibility system is welcomed by the masses at a given place conforms to the level of productive forces there as well as to the level of management and administration there. The choosing and determining of the form of the responsibility system to be adopted certainly must start from the degree of awareness on the part of the masses of people and from practical requirements, upholding the principles of voluntary participation and mutual benefit. In a minority of places, the masses demand that a form of the responsibility system be chosen and determined which suits local conditions, but because individual leaders are inclined to a certain form of the responsibility system, the form that suits the inclination of the leaders is mainly practiced there and the rational desire of the masses is not satisfied. In these places, if the problem of the leadership's ideological understanding is not solved, it will be very difficult to think of the multiformity of the responsibility system. There is another situation, viz, proceeding from the level of the productive forces as well as the level of the cadres' management, there is a given form of the responsibility suited to be carried out at a given place, but at this place either because the cadres' work style is not democratic or because of factional trouble between family heads, a considerable part of the masses demand that a form of the responsibility system that is not too suitable be carried out. Faced with this special situation, we should adopt the methods of persuasion and education and of demonstration of typical cases, brief the masses on the advantages and disadvantages of different forms of the responsibility system, and lead them to choose a comparatively suitable form.

POLICY ON PURCHASE OF FARM MACHINERY DISCUSSED

Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 1, 1982 p 4

["Farm Machinery Current Report" Column: "Several Policy Questions"]

[Text] The 1982 National Farm Machinery Products Purchasing Conference was held in Changzhou city, Jiangsu Province, 1 to 7 December. The vice minister of the Farm Machinery Ministry, Comrade Li Ben [2621 2609], spoke at the opening ceremony. He first talked about the nation's economic situation and the production and sales trends of farm machinery, the guiding ideology of the 1982 production plans and the principles of arrangement. He also expressed opinions concerning several policy questions. He said: In the opinion of the Farm Machinery Ministry, farmers can purchase farm machinery, and in particular, they can make joint purchases of farm machinery. But we must emphasize that this machinery must be used mainly for farming. The machinery can also be used as an aid for the individual in planting and processing and reasonable fees should be levied for its use, but such machinery cannot be shipped to far away places for sale. He said the business use of tractors for transport should be allowed. Agricultural transport constitutes about 50 percent of the total amount of work involved in agricultural production. The time required for transporting goods by tractor is much greater than the time required for planting in the fields. At present, many localities have unilaterally emphasized the prohibition of the use of tractors for business transport. This is an overly narrow understanding of agricultural transport. The line of separation between agricultural transport and business transport is not clear. We believe that agricultural transport should include: transporting earth, manure, and crops in the fields; transporting chemical fertilizers, farm chemicals and such production materials needed by the farmers; transporting coal, food grains and such materials for living; transporting building materials for building houses; transporting agricultural sideline products for submitting to the state; and transporting raw materials and products back to the commune and brigade enterprises. Comrade Li Ben also mentioned some administrative leadership departments in provinces, cities and autonomous regions which have established many regulations concerning purchases by farm machinery companies which prohibit them from purchasing superior quality products from other provinces and cities. This is a regional closed-door policy to protect the backward products of the localities. It is unfavorable to the readjustment of the farm machinery industry and we must oppose it firmly.

PREVENTION, CONTROL OF INSECT PESTS IN STORED GRAIN

Lanzhou GANSU RIBAO in Chinese 15 Apr 82 p 1

[Article by Storage Office, Provincial Grain Department: "Briefing on Several Grain Storage Pest Prevention Methods"]

[Text] Comrade Editor:

Ever since the Third Plenary Session [of the 11th Party Central Committee], great improvement has taken place in the lives of commune members, a small grain surplus gradually accruing. However, on the issue of grain management and storage, experiences and methods are still lacking, and grain in storage has been eaten by insects. My home is in Shangxiao Commune in Zhenyuan County. In mid-November last year when I returned home to visit relatives I discovered that a white (and yellow) powder had fallen beneath the corn that my family had hung up last year and the year before. Upon taking down the ears of corn and taking a look, I found that bugs growing in the corn had hollowed out the kernels causing a very great loss. Similar situations occurred in all the villages in the countryside where we live. Stored wheat also developed bugs and moths that caused varying degrees of damage. Will your newspaper please provide some scientific ways in which grain can be stored and cared for?

Zhao Mingru [6392 7686 0320], Dongxia Mine worker, Huating Mining Bureau

The damage caused to stored grain by insect pests is serious. Prevention and control measures of different kinds must be taken on the basis of their living habits and activities to achieve the goal of early prevention and early cure. Let us now relate several prevention and control methods for consideration by rural communes and brigades and the masses of commune members.

Prevention and Control Through Sanitation and Hygiene. Inasmuch as most insect pests in grain reproduce in damp, dark, and dirty places, in each and every step of the way from harvesting, to husking, to storage, to care, and effective job of sanitation and hygiene must be done. When removing husks, for example, the area must be swept clean, and all surrounding weeds, garbage, and stalks from which the grain has been removed eliminated. Wheat husks should be promptly taken away; the grain to be stored in granaries should be thoroughly sunned, ventilated and screened so that the grain will be dry, clean, and plump. Containers for storing grain and warehouses must be maintained clean and sanitary inside and outside to get rid of all hidden pests and prevent infestation.

Physical and Mechanical Prevention and Control. This means use of the grain's own natural physical properties and mechanical physical function to inhibit growth of insect pests to achieve the goal of eliminating them. Commonly used methods are as follows:

One is the use of high temperatures to kill bugs. Granary mites have a certain range of temperature to which they can adapt, and when temperatures exeed the maximum limits they require, they cannot tolerate them; their physiological functioning is destroyed or stifled leading to their death. In the case of newly harvested peas or wheat, for example, sunning under a scorching sun with the grains spread out to a 2 cun depth and turned once each hour will bring the grain temperature above 45°C. After 2 hours, it can be stored while still hot or placed in containers and later covered with clean straw mats or rush mats. Cloth bags filled with either clean wheat chaff or dry sand can be placed on top of the grain so the grain's temperature automatically drops. After being subjected to heat in this way, the protein in the bodies of the insects congeals causing death.

Second is drying to kill bugs. This entails use of a drying machine to kill bugs by eliminating water. When regulating the temperature and flow of various kinds of drying machines, usually an internal machine temperature of from 80 to 100 degrees centigrade is needed to bring the grain temperature to about 50°C, which will kill the bugs. But grain dried in a dryer has to be cooled before it can be stored; otherwise, unless the heat has been dispersed, calorific molding may accidentally occur.

Third is killing the bugs with cold. During the winter, select a cold, dry, clear day for removing bug infested grain to the outside. Spread it out to a depth of 2 to 3 cun when temperatures are at between 5° and 10°C below zero, turning the grain about once every 2 hours. Ideally this freezing should be done for 5 days and nights, and the bugs will freeze to death. After freezing, the grain should be ventilated and screened to get rid of the frozen and stiffened bugs. Then, while still cold, the grain should be stored in tightly closed containers. In this way all the bug larvae hiding in the grain can be frozen to death.

Fourth is ventilating and screening to eliminate bugs. By subjecting bugs and debris that are lighter than air to the airflow of a fan, they will be blown far away while the grain will drop nearby, and the goal of separating the grain from bugs and debris will be achieved. When bugs are larger or smaller than the kernels of grain screening can be done, the bugs and debris being eliminated by using screens with different size holes, the residue being concentrated in one place for burning.

Fifth, is the gland method. This method is used primarily in provention and control of moths. Since moths mostly lay eggs on the surface of grain heaps where they propagate to become a pest, the gland method may be used to control them. The gland method requires flatening tightness, denseness, and sealing so that adult moths cannot mate and so that there is no room to lay eggs, making reproduction impossible.

There is also the method of luring them to their death. Mostly this takes advantage of the pest's habits to lure it into capture or death. A case in point is the corn weevil [Sitophilus zea-mais], which has a habit of climbing. If straw is bound together to form a handle and the lower end is spread apart to form a parasol shape, and the thing is placed on top of grain, the pest will climb into the straw handle after which it can be burned and deeply buried. Moths usually are phototaxic so if a basin of water is placed on a grain pile in the evening and an oil lamp placed atop the basin, the pest will flutter toward the light and fall into the water and drown.

Oxygen Deprivation Prevention and Control. Dry the grain and store it in a container. After the container is full, seal it tightly to cut it off from outside air and use the physiological metabolic activity of the grain, pests, micro-organisms and such live organisms to gradually reduce the oxygen content of the grain and gradually increase its carbon dioxide content. This creates an oxygen deficiency or a low oxygen content throughout the grain so that the insects pests will be unable to survive. When oxygen concentration in the grain has been naturally reduced, a small amount of aluminum phosphate may be used to help kill the insects, namely 1 to 2 grams of aluminum phosphide per cubic meter. It should be placed in a small cloth bag and buried half a meter deep in the grain where it will serve to kill the insects within 10 to 15 days time.

Chemical Prevention and Control. This method uses toxic materials to directly or indirectly poison pests. It is both effective in killing insects and in preventing or controlling their spread, serving as both a method of prevention and control.

There are numerous chemicals available in the form of powders, liquids, emulsions, smokes, and gases. Each has its own characteristics. For example, powders are compounded from a mixture of a toxicant with pottery clay, talcum powder, and such inert materials. The smaller the powder granules the larger the area covered, the greater the opportunity for pests to come in contact with it, and the greater its power to kill or disable. Fumigating toxicants include chloropicrin and aluminum phosphide. They are characterized by a low boiling point, strong volatility, and the higher the temperature, the faster their spread. Use of these intensely toxic chemicals should be done with the help and guidance of technicians from food units; instructions for use should be strictly followed, and attention given to pertinent points to strictly guard against accidental poisoning of people, livestock, or grain.

ORGANIZATION OF AFFORESTATION EFFORTS DESCRIBED

Lanzhou GANSU RIBAO in Chinese 15 Apr 82 p 1

[Article: "Rapid Progress in Afforestation of Qingyang Prefecture. Clear Perception, Vigorous Action, Leaders Taking the Lead, and Making a Concerted All Out Effort"]

> [Text] Editor's Note: Qingyang Prefecture has done a good job of afforestation this spring and should be commended. Facts have shown that wherever leadership comrades have a clear perception, take vigorous action, and take the lead in work, afforestation proceeds quickly and results are good. It is hoped that all prefectures will now seize the season, will work ceaselessly and untiringly, and fulfill their spring season afforestation tasks.
>
> The four measures for growing seedlings now that the Qingyang CCP Committee has put forward are also very good ones, and can be provided to all prefectures for the lessons they teach.

As of the end of March, Qingyang Prefecture had afforested more than 210,000 mu or 77.8 percent of its afforestation quota for the year. Heshui, Qingyang, Huanxian, and Zhengning counties have already fulfilled more than 80 percent of their afforestation quotas for the entire year. The prefecture has also grown a total of more than 21,300 mu of seedlings. An overall survey of Qingyang Prefecture's afforestation situation shows it characterized particularly by great momentum, rapid progress, and good results.

First the broad masses of cadres and people fully understand the important significance of afforestation and actively devote themselves to this movement by all the people. Statistics show that 750,000 people from cities and town to rural villages throughout the prefecture have joined in the springtime afforestation movement. Arousal of the masses in Heshui County has been relatively complete; within the very short space of slightly more than half a month's time, the county has afforested more than 13,100 mu, overfulfilling its quota for the entire year. Xiangle Commune in Ning County was an advanced unit last year in Qingyang Prefecture, and this year plans call for afforestation of 8,000 mu, 9,849 mu of which was completed this spring.

Second, leadership cadres at all levels personally took part, working while giving directions in the frontlines of afforestation and effectively spurring on the masses. Heshui County CCP Committee secretary Wang Naifeng [3769 0035 1496], and county magistrate Hui Zhenxing [1920 2182 5281] personally surveyed plans and took charge of movement of seedlings. Ning County CCP Committee secretary Zhang Chongjian [1728 1504 0313] walked 60 li from Chengbeichuan to survey the afforestation situation. When he discovered that quality of tree planting was not high in a stretch between Waxie and Chengguan communes, he immediately made an on-site study in conjunction with comrades from the communes, and had the trees replanted. Numerous commune and brigade cadres went into the frontlines of afforestation, made prompt on-site inspections and criticisms, and solved problems, giving powerful impetus to the progress of afforestation.

Third was centralized planning with clear designation of key areas. Seven counties in the prefecture preliminarily designated 32 key communes for afforestation, each of which was charged with afforestation of more than 2,000 mu. The general plan was for one mountain and one ravine, lumped together in a continuous tract for centralized operations of centralized planning, the work being done in individual sections. The key points for afforestation in each county were relatively centralized in terms of leaders, workforces, planting of seedlings, funds, and technical forces.

Fourth was further carrying out of the "three fixeds" policy to promote afforestation and production. Since the lunar new year Zhengyang, Ning, and Zhengning counties newly transferred to commune members 103,600 mu of "three wastelands," and issued 15,800 forest rights certificates.

Fifth was conscientious investigation and handling of cases involving destruction of forests. Recently the prefecture has investigated and disposed of more than 700 cases of various kinds of forest destruction, and some counties and communes have also convened mass meetings to publicly handle, with great fanfare, cases involving destruction of forests in an attack on the evil tendency toward destruction of forests.

Simultaneous with spring afforestation, the Qingyang Prefecture CCP Committee required each county and commune to seize the favorable opportunity and use four methods for handling propagation of seedlings. First was use of state owned nurseries and commune and brigade forest farms for growing them. Second was contracting to individuals of production team reserve land for the growing of seedlings. Third was the signing of contracts with key households for the growing of seedlings. Fourth was requiring each commune household to grow one-tenth of a mu of seedlings.

SPECIAL EMPHASIS DEVOTED TO COTTON GROWING

Lanzhou GANSU RIBAO in Chinese 15 Apr 82 p 1

[Article by Cheng Jingli [7115 4544 4539] and Gao Guangcai [7559 1684 2088]: "Jiuquan Prefecture Diligently Implements Cotton Growing Plans. While Positively Not Relaxing Grain Production, Economic Crops Actively Developed"]

[Text] While stabilizing the grain growing area at 1.27 million mu, Jiuquan Prefecture has taken effective action to actively implement cotton growing plans. As of now, collectives and individuals have planted cotton on an area of more than 91,000 mu.

Jiuquan Prefecture is the province's main cotton growing area. While readjusting the internal structure of agriculture and arranging crop patterns, counties and communes have diligently and equitably put into effect state plans for the area to be sown to grain. Last winter and this spring they perfected and consolidated responsibility systems and signed agreements linked to cotton output with commune members, thereby designating the households and the land for the planned growing of somewhat more than 87,000 mu of cotton and setting up a system of rewards and penalties. In addition to fulfilling cotton growing area plans, the Huancheng, Nancha, and Xihu communes in Anxi County also mobilized commune members to grow more than 1,300 mu of cotton on their private plots.

By way of assuring increased output of cotton, the Cotton and Livestock Products Company and the Supply and Marketing Cooperative paid an advance against anticipated cotton production to communes and brigades. Agricultural science and technology units at all levels went into communes and brigades to conduct 127 runnings of agricultural science and technology courses. They taught the mixing of cotton seeds in pesticides, farming techniques, prevention and control of diseases and insect pests, the "five major prunings" and such techniques, 783 technical personnel receiving the training.

CHICKEN RAISING EMPHASIZED AS FIRST STEP TOWARD ECONOMIC DIVERSIFICATION

Lanzhou GANSU RIBAO in Chinese 5 Apr 82 p 1

[Article by Gao Guangcai [7559 1684 2088] and Fan Yongyi [2868 3057 5030]: "Combination of Farming, Livestock Raising, and Processing To Make Rural Economy Prosper. Jiuguan Prefecture Resolutely Changes Inequitable Agricultural Structure"]

[Text] Following a summary of experiences, Jiuquan Prefecture has resolutely changed its inequitable agricultural structure. While guaranteeing fulfillment of state commodity grain quotas, it has taken the road of simultaneous development of grain and livestock in a combination of farming, livestock raising, and processing in order to promote large scale development of the rural economy.

Jiuquan Prefecture is one of the major commodity grain bases in Gansu Province. Conditions here are suited both to the growing of grain and to development of economic diversification. During the past 2 years, some representative communes and brigades with all around increases in output and earnings have come into being. The Prefecture has decided that while guaranteeing fulfillment of state commodity grain quotas, it will change the old methods of the past of relying on sales of excess grain and take the new road of simultaneous development of grain and livestock in a combination of farming, livestock raising, and processing.

In order to do this, it has put forward four specific actions to be taken. One is to give support to development of key households and specialized households for the raising of livestock and poultry in an effort to increase peasant earnings from the breeding industry throughout the prefecture. Second is to guide commune members in good farming practices on their private plots, on land devoted to the growing of animal fodder, and on forest and grass lands. Third is concentrated emphasis on the "four plantings" (of cotton, soybeans, grapes, and compound grasses [5112 0678 5430], the "four raisings" (chickens, hogs, sheep and goats, and rabbits), and the "four processings" (pressing oil, compound livestock feed, bean products, and sewing), and the "one circulation" (development of collective businesses) in an effort to outstandingly increase earnings this year from economic diversification. Fourth is funds for development of economic development, most of them to be taken from commune and brigade collective accumulations while at the same time encouraging commune members individually to invest in shares for the running of joint operations.

Before spring farming got underway, the prefecture held a series of rural work conferences to discuss these measures and to unify understanding about them. Once spring farming got underway, leadership comrades at the prefecture and county levels went down into the frontlines to supervise, encourage, and inspect, and to put planting plans into effect on production teams and households. In addition, they adapted general methods to local situations, gave tailored guidance, and began to establish more than 30 individual economic diversification bases in order to assure fulfillment of plans for "hot-selling" products. Focusing on the weak link of the breeding industry in the prefecture, they proceeded from the basis of overall planning to make a breakthrough in chicken raising. County and commune leadership and specialized cadres, led by an assistant director, made the rounds of 18 hatching points, held on-site discussions, and made on-the-spot decisions, very quickly putting to work more than 2,000 key chicken raising households and specialized households. This spring the prefecture hatched 600,000 fine quality eggs from more than 400,000 hatch chickens. Counties and communes, communes and brigades, brigades and households signed contracts level by level for the hatching and feeding of chickens, and received support in funds, feed, and techniques.

BRIEFS

JIUQUAN PREFECTURE FARM MACHINERY--The eight farm machinery enterprises in Jinquan Prefecture, Gansu Province, actively implemented the policy of readjustment, improved business management, changed the business management method, and readjusted the structure of products. They actively expanded light industrial and civilian machinery products, developed diversification, contracted work to process incoming raw materials, and at the same time, implemented various forms of the economic responsibility system and realized good results. In 1980, the total production value of the whole prefecture surpassed the annual plan by 38 percent, realized a profit of 329,000 yuan, and created the best profit level of the past. From January to August of 1981, the total value of industrial production completed reached 3.18 million yuan, constituting 71.6 percent of the annual plan and a profit of 100,000 yuan. The 1981 profit goals were realized with a surplus 4 months ahead of schedule; every enterprise realized a profit and suffered no losses. [Text] [Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 1, 1982 p 5] 9296

SEED PLANTING HOUSEHOLDS INCREASE--Tianshui Prefecture seed units at all levels have vigorously developed seed growing households this year and signed technical contracts early with seed growing households for experiments with fine seed varieties, for bumper yield demonstrations, for fine seed propagation, and for extension of seeds to use in farming. Now the number of seed growing households in the prefecture has grown to 6,657 households, three times more than last year. Last year, Ping'an Commune in Zhangchuan County designated 181 households as fine variety propagating households for "xiaobaihua" potatoes on an area of 188 mu. Results were a yield averaging 3,076 jin per mu from the propagating fields, a 1.64 fold increase per mu as compared with local variety, "Changshu No 4." This year this commune has required an increase to 293 in the number of households undertaking propagation of fine variety, "xiaobaihua" and an expansion of the growing area to 300 mu. The propagation area in the prefecture for "Zhongdan No 2" fine variety corn has also been increased from last year's somewhat more than 40,000 mu to this year's 140,000 mu. BRIEFS

PEASANTS' INCOME INCREASES--In Guangdong Province, the rural economy has quickly improved and peasants' income has remarkably increased. In the province, the total income of rural communes, not including fishery communes, last year was 23 percent more than in 1980 and the income distribution to commune members was 28.3 percent more than in 1980. The per capita income distributed by the collective was 130 yuan, 26.2 percent more than in 1980. The per capita income of commune members derived from household sideline production was 85.7 yuan. Thus, the per capita income in rural areas in the province last year reached 215.7 yuan. [Text] [HK101417 Guangzhou Guangdong Provincial Service in Mandarin 100 GMT 8 Jun 82 HK]

SOME THOUGHTS ON DEVELOPMENT OF FORESTRY IN GUIZHOU

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 2, 1982 pp 41-43

[Article by He Tingxian [6320 1649 7359], Guizhou Provincial Department of Forestry: "Cursory Remarks on the Issue of Making Most of Guizhou's Forestry Industry Advantages"]

[Excerpts] Guizhou Province has extremely abundant forestry resources. A discussion of major kinds of trees follows.

One is China fir. China fir is the tree principally used for lumber in Guizhou, accounting for between 70 and 80 percent of commodity lumber over the years. Guizhou has a long history of growing China firs, the regional distribution of which is very widespread. Ninety percent of the province's counties produce China fir.

One of China fir's outstanding characteristics is its rapid growth. It reaches maturity in 10 to 20 years and is a rapidly growing variety of tree in Guizhou. A survey of 44 base forest sites shows 11 year old China fir reserves to average 15 cubic meters per mu, the minimum being 10.57 cubic meters and the maximum being 19.3 cubic meters.

Still another China fir characteristic is good quality lumber with high utilization value. Guizhou's "nursery stock" has long enjoyed brisk sales both at home and abroad, and is very competitive. Right now a China fir coffin commands $1,500 in the Hong Kong market. In China markets, 1 cubic meter of China fir has a value of 400 yuan and can be exchanged for 2,000 jin of rice.

Second is tung oil trees. Guizhou Province's tung oil tree output is second only to that of Sichuan Province putting it in second position nationally. It is a traditional Guizhou export commodity that has always enjoyed a high reputation in international markets. Guizhou Province's tung oil trees have an 87 percent commodity rate and a 34 percent foreign exchange rate.

Tung oil trees possess strong adaptability, fruit early, and provide many benefits. The peasants praise them saying, "If a family has 1,000 tung oil trees, its sons and grandsons will never be poor." Currently more than 60 counties grow tung oil trees over an area totaling 4.2 million mu. During the past 3 years state procurement of Guizhou tung oil tree seeds has averaged 130 million jin, 67 percent of the gross output value of economic forests.

Third is raw lacquer. Guizhou Province's raw lacquer output now ranks fourth in the country. It is a renowned traditional Chinese export commodity. Seventy counties in the province produce lacquer, most of it in Bijie Prefecture. Dafang County's lacquer has a pungent smell and fine texture; it is called "genuine lacquer." "Genuine lacquer's " quality is the best in the country and renowned both in China and abroad. It is sold widely in Japan and the countries of southeast Asia. People say that "genuine lacquer is as clear as oil; it's brightness reflects a person's head; its color flashes like the stripes on a tiger; and it calls to mind fish hooks." Raw lacquer has high economic value. Export of 1 jin of raw lacquer is equivalent to 105 jin of wheat. Growing of 1 mu of raw lacquer is the equivalient of growing 6 mu of wheat.

Development of forestry plays an important role in maintaining ecological balance in developing agricultural production, and in improving the lives of the people. The forest cover rate in Qiandongnan Autonomous Zhou is 27.7 percent. For every mu of cultivated land there are 4.4 mu of forest shelter; consequently erosion is less than 10 percent. Paddyfields account for 75 percent of the zhou's cultivated land area; the effective irrigation rate is 56 percent; the assured irrigation rate is 42 percent; drought rarely occurs; and grain outputs are relatively high and relatively consistent. Between 1971 and 1978 three great droughts occurred, yet grain output for the zhou as a whole increased by 211.19 million jin, a 14.4 percent increase. In seven key forest area counties (Liping, Rongjiang, Congjiang, Mianping, Tianzhuang, Leishan, and Jianhe), average extent of increase was 26 percent, which was 11.6 percent higher than for the average rate of increase for the zhou as a whole. The greatest increase in output occurred in Rongjiang County, which had a 39 percent increase.

Guizhou Province's forest cover rate is only 14.5 percent. Calculations made from hydrological data show an annual discharge into the Chang Jiang and the Zhu Jiang of more than 61 million tons of silt for the province as a whole (in 1978 it was 79.6 million tons), or an average 1.3 tons per mu of cultivated land. This means an accumulated loss of 26 tons per mu for the past 20 years, equivalent to the denuding of the soil's surface horizon to a depth of 1 cun. This runoff of silt contained more than 480,000 tons of nitrogen, phosphate, and potash, more than the province's annual output of chemical fertilizer. As a result, the area of infertile soil increases year by year. Accoring to the first soil survey done in the Qiandong Autonomous Zhou in 1959, infertile soil accounted for 20 percent of the zhou's cultivated land area. Survey statistics from the second soil survey in 1976 showed infertile soil to account for 42 percent of the zhou's cultivated land area, a more than onefold increase. In the 15 year period between 1961 and 1975, as a result of the destruction of forests to clear land for agriculture and soil erosion, rock mountains in Qingzhen County increased by 77,470 mu, accounting for 3.5 percent of the total area. Still another characteristic of Guizhou Province's natural geography is a karst topography area of more than 70 percent. In most places atop the limestone is a layer of sandstone, sandy shale and Quarternary Period clay cover. When these areas have no forest cover, the underlying limestone very quickly becomes exposed to form "barren land." Limestone is extremely resistant to weathering, and its weathering to form soil takes a geological age. If the ecological environment of this more than 70 percent of the area continues to deteriorate, without doubt the very existence of the people will be threatened, and they will suffer the penalty of nature. Guizhou Province is also situation on the eastern escarpment of the Yunnan-Guizhou Plain where the water system is spread over a wide area. Consequently, the natural ecological balance of the forests not only functions to influence the province's agricultural and livestock production, but also influences the industrial and agricultural of the middle and lower reaches of the Chang Jiang and the Zhu Jiang. The silt content of the Hongshui River in Guizhou Province is second only to that of the Huang He. This poses a severe threat to the middle and lower reaches of the Zhu Jiang. As a result, making the most of Guizhou Province's forests, expansion of the forest area, and maintenance of the natural ecological balance poseess extremely great importance.

3. Several Problems Urgently in Need of Solution in Making the Most of Forestry

First of all it is necessary to currectly understand and correctly handle the relationship between grain and forests. At the present time the contradiction between forests and grain is conspicuous. Right now some places are uanble to very well make the most of forestry's advantages. They are frequently preoccupied with grain problems and fear that forestry will impair grain production. Guizhou Province has a large population relative to cultivated land, and yields per unit of area are low. In some mountain regions, each person has only several tenths of a mu of cultivated land, but there are 10 mu or several tens of mu of barren mountains per capita. This situation demands that we do a good job of scientific farming, increasing total grain output by increasing yeilds per unit of area. It also requires that we keep our eyes on widespread use of mountainlands for the development of forestry lumber, and forest byproducts that can be exchanged for grain. Because commune member food rations are inadequate in the forest region of Jinping County, annually 10,000 mu of forest are destroyed and the land cleared, and 2,000 mu of forests are destroyed to make farmland. In 1980, with policy permission, 2,000 cubic meters of timber outside plan were exchanged with other provinces for more than 4 million jin of rice to supplement commune member rations in forest areas and the destruction of forests greatly decreased.

Second is emancipation of the mentality and liberalization of policies. For forestry to advance, principal reliance will have to be placed on arousal of peasant enthusiasm. The main problems in our present policies for handling lumber and characteristic native sideline products are fairly heavy uniform purchase and requisition purchase quotas with virtually stifling control. Thus, one current major problem in making the most of forestry's advantages is further emancipation of the mentality and liberalization of policies. So-called liberalization means self-determination under guidance of the state plan in forestry production, with definite distribution rights for products.

Once state plans or contract quotas have been fulfilled, policy should permit self-determination in how excess timber and forest by-products are handled, so they may be exchanged for needed production and consumer goods.

Privately retained mountains act as a supplement to the socialist economy and posses extremely important significance of satisfying commune member livelihood needs, for hastening afforestation, and for protecting the fruits of collective forest operations. The Guizhou Provincial CCP Committee and Provincial People's Government have ruled that wherever conditions permit, 3 to 5 mu may be designated as privately retained mountain for each commune and brigade household. Where more barren mountains exist, more land can be so designated. There are about 20 million mu in the province that should be designated privately retained mountainland. Privately retained mountainland, first of all, requires not investment by the state; and, secondly, without any undue bother on the part of the collective within 2 or 3 years these barren mountains and wasteland slopes will begin to be afforestated.

Third is overall planning and equitable distribution. To make the most of advantages forestry offers, matters must be handled in accordance with natural and economic laws with adaptation of general methods to suit local situations, strongpoints highlighted, and major efforts made to build commodity forest bases. Building of such bases requires specific scientific plans. The turnover period for forestry production is long, so it will not do to have only short range plans; long range plans will be needed too. Moreover, once a plan has been formulated, it should not be lightly changed. If one-fourth of the province's existing more than 100 million mu mountain area suited to the growing of forests were to be alloted for the building of high standard commodity lumber forests and economic forest bases for the production of tung oil trees, raw lacquer trees, Chinese tallow trees and tea oil trees, and if they were intensively farmed in the same way as grain is grown, being given meticulous care, the value of economic forests and fast growing timber forests per mu would be three to seven times greater than the value of 1 mu of farm crops. The value such bases created would be, at minimum, equal to that of the province's 30 million mu of cultivated land; mountain regions would prosper very quickly; and the economic income of the province as a whole would greatly increase. The masses say it well when they say, "The way to bring prosperity is to develop the province's forestry."

Fourth is to take the integrated route of operating integrated forestry, industrial, and commercial enterprises. Throughout the province 39 integrated forestry, industrial, and commercial enterprises have been operated by state owned forest farms by themselves or in conjunction with neighboring communes. Another 18 integrated forestry, industrial, and commercial enterprises have been operated jointly by communes and brigades in mountain regions. Though the trial run period has not been very long, prospects for this new thing have unfolded before our eyes and a very large number of advantages have become evident. One is that they help implement a program based on forest farming to advance forest production and improve the material living standards of the masses. Second is that they help make full use of forest resources, save timber, support national construction, and satisify the needs of people's livelihood. Third is that they help strengthen centralized management of forests in a change of the current administration by many different units and the situation of rampant cutting and denudation. Fourth is that they help use economic methods to include commune and brigade forestry products in forestry, industrial, and commercial enterprises; they centralize processing and use; and they strengthen the collective economy. Fifth, forestry units are able to earn a fair profit, which helps expand forestry reproduction. In short, development in the direction of comprehensive forestry, industrial, and commercial operations is a trend in the modernization of forestry and an objective requirement for economic development.

LEADERSHIP FOR FIGHT AGAINST DROUGHT STRENGTHENED

Chijiazhuang HEBEI RIBAO in Chinese 14 Apr 82 p 1

[Article: "Cangzhou Prefecture Cadres, Masses Cooperate to Fight Drought"]

[Text] In Cangzhou Prefecture, the key issue of setting up rural grassroots leadership teams has been ferociously taken in hand to do a solid job of the "one resistance and double contracting systems" [a system of fixing output quotas on households and a system of peasant households assuming full responsibility for task completion]. As of now the prefecture has already watered 1.65 million mu of land that was not plowed following the last harvest. This is more than 1 million mu more than was watered during the same period last year.

In more than 700 production brigades, the unplowed land has been given one spring watering, and more than 70 communes have watered more than half the land. The pace of fertilization, cultivation, and hoeing of wheatfields has also been faster than during the same period last year. By way of solving problems of "decentralized organization, chaotic ideology, and fatuous work style" in rural grassroots leadership teams, the Cangzhou Prefecture CCP Committee and government administrative offices launched a campaign of "one resistance and double contracting," and too three actions as follows: First was maintaining virtually stable the grassroots cadre corps. This meant that the "four kinds of people," and the "three kinds of people" had to be resolutely done away with. Where readjustment of a small number had to be made, the readjustment was strictly attended to. Cadres who had been promoted overly fast but did their work well did not necessarily have to be readjusted. When no readjustment of others was required, leaders explained matters clearly to them face to face so that they could be free from anxiety and devote themselves to their work. Second, each echelon set up responsibility systems for level by level action. Responsibilities were strictly and impartially defined; rewards and punishments were clearly delineated; the advanced were commended, and the laggards helped to advance. Third was strict attention to solving the matter of production team cadres abandoning their responsibilities. Following reorganization, these leadership teams actively led the masses in launching struggle against drought to hasten the pace of the fight against drought.

CONDITION OF WHEAT SEEDLINGS, HARVEST PROSPECTS EXAMINED

Shijiazhuang HEBEI RIBAO in Chinese 8 Apr 82 p 1

[Article: "Wheat Seedling Situation Takes Favorable Turn, but Only Continuation of Intensive Care Can Win Bumper Harvest. Deputy Director of Provincial Bureau of Agriculture and Agronomist Gong Bangduo [7895 6721 6995] Talks About Technical Care of Wheat at the Present Time"]

[Text] Recently specialized technical cadres from agricultural bureaus and in the four prefectures of Handan, Xingtai, Shijiazhuang, and Hengshui and from the Provincial Crop Institute formed a southern area wheat examination team for the examination of current wheat seedling growth and care, and to put forward ideas for future technical care. Now I will talk about the following several views:

Thanks to early action in spring wheat care, to strict attention, and to good care, great changes have taken place in wheat seedlings since they greened up, and everywhere there has been a turn for the better. Right now the seedling situation approaches that of the same period last year. This is demonstrated in three ways: First is early greening up, numerous new tillers, and fairly rapid growth of plant colonies. Generally, greening has occurred about 10 days sooner than last year; the number of tillers has increased by from 100,000 to 200,000 per mu as compared with before the onset of winter, an average of 150,000 per mu. As compared with last year, the gap between wheat plant colonies has become increasingly small, and some have surpassed last year. According to statistics from Handan, Shijiazhuang, and Hengshui prefectures, before the onset of winter last year, but by the time growth got underway, they were only 20,000 fewer. Reports from four prefectures indicate that in 17 counties the wheat seedling situation is currently somewhat better than last year; in 16 counties it is about the same as last year; and in 18 counties somewhat poorer than last year. A look at the situation in four counties shows the total number of tillers during the winter to have been 180,000 fewer than in 1980, but only 53,000 fewer now. A look at the situation in 12 production brigades shows tillering to be about the same or slightly better than in 1981. Second is maintenance of greenness throughout the winter, light freeze damage, and few dead seedlings. Last year the wheatfield area in which the dead seedling rate was more than 10 percent in the four prefectures covered 3.18 million mu, but this year, as of now, the dead seedling areas covers only

210,000 mu. In four counties last year the dead seedling area covered 217,000 mu, but this year there are virtually no dead seedlings. Third, the differentiation period for wheat has been protracted. This helps formation of large spikes and an increase in the number of grains. Since the greening up stage came early this year and temperatures tended to be low again during the last half of March, the spikelet differentiation period was lengthened. In addition, there was little depletion of soil fertility before the onset of winter and quite a bit of nitrogenous and phosphate chemical fertilizer was applied, so reserve strength is available for the wheat, and the number of spikes and grains may increase.

Though beneficial factors have been fairly numerous and changes in seedling condition fairly large since the lunar new year, some problems also exist that must arouse a high degree of serious concern. One is that the drought situation is presently very serious. Though it rained several times this spring, in most places the amount of rainfall was not great, generally less than 20 millimeters. For a considerable portion of the wheat, soil moisture conditions are very poor. Water content in dryland wheat soil that has not been watered is less than 10 percent. For soil watered once during the winter, water content is also only 12 to 13 percent, posing serious threat to wheat growth. In addition, because above ground water sources do not suffice and the ground water table has fallen, the wheatfield area that can be watered and the frequency of watering will be seriously affected. A second is that though wheat colonies are about what they were last year, growth of individual plants has been rather poor. Wheat tillering this year has been characterized by much spring tillering and little winter tillering; numerous small tillers and few large tillers; little secondary root growth, and a possible drop in the tillering and full heading rate. Consequently maintenance of last year's number of spikes per mu will also be very difficult. A third is wheatfield care has been uneven from place to place. Some places got started late and progress has been slow. They have yet to finish the first watering, and their wheat care tasks are very great. Therefore, the task of winning a bumper wheat harvest this year will be a very arduous one.

The winning of a bumper summer harvest will require continued efforts and genuine improvement in mid and late season wheat care. In view of wheat seedling condition and problems that may crop up, wheat field care during the mid and late season will particularly require attention to "one combat," and "two improvements." The two improvements mean improvement in the spiking rate and improvement in the fruiting rate. Now let us propose several points for care during the jointing season.

First is timely watering for jointing. Measurements show that during the jointing season, wheat's need for moisture suddenly increase to three times the volume of water consumed during the greening season. The volume of water needed from the jointing to the spiking stage amounts to one-third the total water requirements. There can be no stinting on water during this period. If water is lacking, the spiking rate and the fruiting rate will decline. Experiments conducted by the Hengshui Prefecture Institute of Agricultural Science show that when watering has been done only once, a watering for jointing increases yield by 62 percent; water for spiking increases yield by 20 percent; water for greening up increases yield by 18 percent; and watering during freezing weather increases yields by 16 percent, yield increases from watering during jointing being most spectacular. Therefore, no matter whether the wheatfield is a high yield, medium yield or low yield one, all available means should be used for timely watering during jointing.

Secondly, during jointing, topdressings of fertilizer should be applied in accordance with seedling conditions. During jointing, seedling conditions vary very greatly and early deterioration is to be guarded against, as is continuation of the vegetative growth stage without entering the reproductive growth stage, and late ripening. Top dressings of fertilizer should be given according to the "three regards," namely regard for soil fertility, regard for fertilizer formerly applied, and regard for wheat appearance and growth. When soil fertility is poor, little fertilization given earlier, and wheat seedling growth weak, some chemical fertilizer may be applied. When soil fertility is good, much fertilizer was applied earlier, and seedlings are growing well, only a slight amount of fertilization should be done. It is necessary to understand the right time and the right amount to prevent topdressings that come too late or in overly large quantities resulting in continuation of vegetative growth and late ripening, with damage from hot dry winds in the late stage, which is bad for increasing grain weight.

Third, late and weak seedlings generally develop late, mature late, and are prone to the bad effects of hot dry winds, which cause a loss of grain weight. Therefore, it is necessary to do more cultivating and hoeing to increase ground warmth so as to promote early development and rapid growth of the wheat seedlings.

Fourth is attention to prevention and control of wheat diseases and insect pests. According to a provincial insect forecast, a large incidence of wheat aphids is likely this year, requiring a high degree of attention. In addition, precautions should be taken against red spiders and wheat rust. Should they suddenly occur, they should be brought under control at once. Diseases and insect pests should not be allowed to impair the per 1,000 grain weight and reduce yields.

In addition, because of the seriousness of the drought, increases in yields will depend primarily on watering, so full advantage should be taken of watering. Special attention should be given to watering and care of wheatfields. In irrigated lands emphasis should go to tapping potential for increased yields from medium yield counties, medium yield communes, medium yield brigades, and medium yield plots. A look at the situations examined on this occasion shows that in all medium yield brigades that implemented responsibility systems, the wheat seedling situation was better than during the same period last year. Water conservancy conditions in these brigades were pretty good and potential for increased yields was fairly large.

However, right now levels of output are fairly low and scientific farming levels are poor. With further improvements in responsibility systems, increase in the level of scientific care for wheat, and attention to implementation of conventional technical measures for tending wheat, a fairly great increase in yields can be obtained.

NEED FOR COLLECTIVE ACCUMULATION, WITHHOLDINGS STRESSED

Shijiazhuang HEBEI RIBAO in Chinese 14 Apr 82 p 1

[Article by Liang Yuncai [2733 0061 2088]: "Do a Good Job of Collective Withholdings for Expansion of Agricultural Reproduction"]

[Text] Recently we conducted a survey in some of the counties in the province on how to further improve and perfect agricultural production systems of responsibility. In the course of the survey, we discovered a general disregard for the role of production teams in the collective economy and a lack of attention to collective withholdings. For example, in some production teams practicing a responsibility system whereby peasant households assume full responsibility for task completion, collectively owned property had been divided up. In an overwhelming majority of production teams, when year end distributions were made little was withheld for the collective. No withholdings of public accumulations funds were made for expansion of reproduction and no public welfare funds were withheld for improvements and increases in worker cultural welfare facilities. This has seriously impaired the consolidation and development of the collective economy of people's communes, and hurt progress in expanding agricultural reproduction.

These problems have many causes, but the main one is that some rural cadres suppose that with the practice of a system whereby peasant households assume full responsibility for task completion, commune members can "continue to revolve by themselves without being greased," and that there is no longer anything for cadres to do. Consequently, they let go and do nothing further. Some of the masses suppose that following assumption by peasant households of full responsibility for task completion, it is a case of a blind man playing a violin, i.e., fending for oneself, and that production teams are no longer useful. These problems are largely a reflection of a small-scale agricultural economy mentality of self-sufficiency.

One has to fully understand that following the practice of responsibility systems whereby peasant households assumed full responsibility for task completion, production teams became a collective economic organization that continued to be responsible for organizing and managing production with authority to distribute the fruits of production, and that they are important integral parts of the collective economy of people's communes. Doing a good job of collective withholdings and strengthening and consolidating the collective economy of people's communes is of extremely major significance for development of agricultural production and for the modernization of agriculture.

Objectively speaking, the responsibility system whereby peasant households assume full responsibility for task completion with workers carrying on small-scale decentralized operations is necessary for developing the level of productivity. However, its historical limitations should also be appreciated, and particularly that from a long-range point of view it restricts agricultural development to a certain extent. Consequently, in practicing agricultural responsibility systems, and particularly when production teams institute responsibility systems whereby peasant households assume full responsibility for task completion, the responsibility systems should function to consolidate the production teams' collective economy and to strengthen the collective economy.

Good performance in collective withholdings is a major way in which to consolidate and strengthen the socialist collective economy and to bring about expansion in agricultural reproduction. Collective withholdings are a part of the collective's centralized distributions. They are an important integral part of the correct handling of material benefit relationships among the state, the collective, and individual workers; they are a manifestation of workers' common benefits and long-range benefits; and they are a major source of funds for production teams' collective accumulations for the expansion of reproduction. Only when collective withholdings are properly handled can the collective economic forces steadily be consolidated and strengthened, and worker confidence in taking the collective road be strengthened.

There is no denying that responsibility systems have effectively solved the problem of "eating out of a large common pot," and have aroused the enthusiasm of workers. If along with the steady perfection and improvement of responsibility systems there is no increase in collective accumulations and no efforts to add new means of production or adopt and promote advanced techniques, the positive role of responsibility systems will gradually dissipate, and worker enthusiasm will also be impaired and limited, causing the pace of agricultural production to slacken. Therefore, in the development of agriculture, it is necessary to rely both on policies and on science. Reliance on policies stirs the enthusiasm of both the collective and in individual workers; reliance on science further emancipates and develops productivity. The widespread use of science and technology can promote tremendous development of productivity. In order to develop science and improve production capabilities, a certain amount of funds are required, and this requirement means steady accumulations.

In a system of responsibility whereby peasant households assume full responsibility for task completion, in order to get the workers to accumulate products surplus to their consumption requirements, collective withholdings are necessary. Only when a good job of collective withholdings is done can expansion of reproduction be assured.

A look at the substance of collective withholdings shows a five part content. First is the portion used to make up for the means of production that have been consumed. This is withheld in the form of depreciation allowances. Second is the additional part of accumulations needed to expand reproduction, which is withheld in the form of public accumulation funds and is the major source of funds for production teams to expand reproduction. The third portion is production expenses withheld to sustain reproduction in future years. The fourth portion is a reserve fund for use in meeting unfortunate accidents or natural disasters. The fifth portion is livelihood welfare funds and insurance funds established to satisfy the workers' common needs and for those who have lost their ability to work. This portion is withheld in the form of public welfare funds. The amount of each portion is decided on the basis of prevailing production team and worker financial strength and experiences over the years. We are against using a method whereby worker consumption is sacrificed without concern for objective realities to get social accumulations. We are also against concern only for present benefit and not caring about long-term benefits, dividing up until it is gone "rice for a meal and firweood for one cooking." There should be no small agricultural economy mentality of no collective accumulations.

Some people suppose that with the practice of a responsibility system whereby peasant households assume full responsibility for task completion and whereby individual households independently complete the entire production process from sowing to harvesting, there is no need for collective withholdings; withholdings can be the responsibility of individual commune member households and there is no need for production teams to handle them. They suppose that collective withholdings by production teams often set up a situation in which some cadres can eat more and take more. There is a certain amount of truth in such talk. In places in which cadre management levels are low, individuals do indeed eat more and take more, swallowing up collective property. However, this is not a shortcoming of the collective economy per se, but rather happens to be a manifestation of a lack of perfection in our collective economic system. We can solve it through democratic management of the eocnomy and through democratic management of fiscal matters as well as through the country's laws. We positively cannot fear doing a thing because of possible problems, not making collective withholdings or operating a collective economy in consequence. We know that each individual household can indeed make accumulations. But the strength of individual households is puny, and both materials and financial resources are limited. No outstanding results can be obtained within a short period of time. But when the dispersed funds of a myriad of households are accumulated in a single place, within a short period of time, copious funds can be assembled. Therefore, not only can we not negate the collective economy or slight the role of the collective economy, but rather we should consolidate and strengthen the collective economy, do a good job of collective withholdings, enlarge collective accumulations, assure expansion of agricultural reproduction, and promote high speed development of agricultural production.

TIPS PROVIDED ON PROPER WHEAT FERTILIZATION

Shijiazhuang HEBEI RIBAO in Chinese 8 Apr 82 p 1

[Article by Liu Jinying [0491 6855 5391], Heli Commune, Wuqiang County: "Problems To Be Watched When Fertilizing Wheatfields"]

[Text] It is not a case of the more fertilization the better. In some places, once the wheat has greened up, large amounts of ammonium carbonate, urea, and such chemical fertilizers are applied at each state, several tens of jin or even more than 100 jin at a time, in the belief that the more the better. The result is a loss of capital without being able to increase yields, but rather causing the soil to become leathery, causing the wheat to remain in the vegetative stage and ripen late, and a decline in the per 1,000 weight of grains. Just what is the reason for this? Just how much fertilizer wheat needs in order to grow is a matter of what is a reasonable amount. Take wheatfields of moderate fertility, for example. The total amount of nitrogen (in terms of scalar quantity) used, including supplemental fertilization and topdressings before the onset of winter, should be no more than 20 jin per mu. About 35 jin of urea is also about right. Specifically in the course of spring care, when the wheat is watered for greening up, about 15 jin per mu of urea or about 40 jin of ammonium carbonate can be applied. When the wheat joints, between 7 and 10 jin per mu of urea can be applied. If ammonium carbonate is used, the amount should be 20-odd jin per mu. Consequently, top dressings of chemical fertilizers should be decided on the basis of the actual condition of the soil.

It is not the case that any way of fertilizing will do. One often sees just any kind of fertilizer being scattered on the ground by some commune members. This way of doing things saves work, but it does not produce the full effectiveness that the fertilizer should produce. Surveys and measurements have shown that if ammonium carbonate or ammonia water chemical fertilizers are put on the surface of the ground, as much as 20 percent or more of it may be volatilized. This artificially creates losses. Consequently, these kinds of chemical fertilizers have to be applied deeply into the soil. If the chemical fertilizer is put only 3 to 5 centimeters deep into the soil, it will be much more effective than if thrown on the surface of the ground.

It is not a matter of indiscriminate fertilizing with nitrogenous fertilizer. In some places, nitrogenous fertilizer is applied with no concern about the wheat's growing stage. This way of doing things frequently leads to the wheat continuing vegetative growth in its late stage, with late ripening and no increase in yields. Experience has shown generally that during the early stage of wheat growth, i.e., during the stages of wheat seedling growth before the onset of winter, during overwintering, when greening up, when beginning growth, and when jointing, the main line of attack should be toward nurture of sturdy seedlings, promotion of tillering, tiller formation, and spiking, and nitrogenous fertilizers such as urea or ammonium carbonate should be applied. But once the wheat has flowered and come into milk, the main line of attack should be directed toward formation of large heads and big grains. During this growth stage, heavy fertilization with phosphate should be done. This will not only increase the per 1,000 weight of grains and make the wheat grains plump, but it will also help the wheat resist lodging and hot dry winds.

POINTERS OFFERED ON MACHINE SOWING OF COTTON

Shijiazhuang HEBEI RIBAO in Chinese 9 Apr 82 p 2

[Article by Maintenance Department, Provincial Bureau of Farm Machinery: "Some Suggestions About Good Cotton Machine Sowing Techniques"]

[Text] The cotton sowing season will soon be here. Machine sowing makes for evenly spaced seedlings and quick sprouting, so the masses like it very much. Let me now make a few suggestions about techniques for doing a good job of machine sowing of cotton, for the reference of all jurisdictions.

1. Before sowing begins, cotton sowing machines should be completely repaired and maintained. It is particularly important that devices for furrowing and regulating planting depths meet agricultural needs. The depth of furrow made by the furrowing device should not exceed 5 centimeters or be any less than 3 centimeters. When the furrowing device is in the down position, the four furrowing parts should all be in the same horizontal plane, rather than some high and some low. When sowing to combat drought is to be done, a soil separating device may be mounted on the furrowing device.

2. Proper regulation of number of seeds sown. First the planter should be set and then readjusted during actual operation. No matter how it is adjusted, the speed at which the wheel revolves has to match the speed of motion of the tractor at the time of planting. When seeds have been treated, adjustments have to be done in accordance with the increase in seed weight following treatment. When sowing, consideration must be given to whether the tractor slides when in motion, and when setting the quantity of seeds to be sown, a 5 to 8 percent increase in amount should be made in accordance with circumstances. In order to avoid clogging when sowing, the cotton seeds should be picked over and all foreign materials removed so that the seeds will be sown smoothly.

3. When sowing, in addition to maintaining the machines as they should be maintained, mud that sticks fast to the drive wheel or roller should be removed at once. Tractor speed must be kept constant with no speeding up or slowing down. At a fast speed, fewer seeds are sown, and at a slow speed

more seeds are sown. Measurements show that 15.6 percent fewer seeds are sown in third gear than in second gear.

4. Field plots to be sown by machine should be nicely harrowed so that their surface is crumbly and they are firm underneath.

BRIEFS

QUEZHOU COUNTY WHEAT--Shijiazhuang, 18 Jun (XINHUA)--Thanks to dissemination of scientific research results, both total output and per-mu yield on more than 300,000 mu of wheatfields in Quezhou County, Hebei, this year have increased by 20 percent over last year. The county has sunk nearly 1,000 wells, dug ditches with a total length of 400 km, leveled 120,000 mu of land and planted 3.7 million trees to harness 230,000 mu of saline-alkaline land in the northern part of the county. BRIEFS

GRASS BORER CONTROL--According to Heilongjiang Ribao, since 5 June a large amount of grown grass borers have emerged in Harbin municipality and in Shuangcheng, Wuchang, Acheng, Fuyu, Bin, Anda, Qingan, Hailun and Suiling counties. According to an investigation on 6 June in suburban Harbin by the Provincial Plant Protection Department, there are 150 to 250 grown grass borers for each square meter of grassland near cultivated areas. Some 100 percent more than in 1980 when borer pests were serious. [passage omitted] The peak period for grass borers in our province is during the last 10 days of June. The Provincial Plant Protection Department has issued notices to various localities urging them to pay close attention to the growth of grass borers and take proper measures to contol them. SPRAYING WITH POTASSIUM DIHYDROGEN PHOSPHATE TO PREVENT HOT WIND DAMAGE REPORTED

Beijing RENMIN RIBAO in Chinese 24 Apr 82 p 2

[Article by Correspondents Wu Chengde [2976 2052 1795] and Wang Biao [3769 1753]: "How Does Henan Guard Against Hot Dry Winds?"]

[Text] Hot dry winds frequently seriously damage bumper harvests of wheat. In recent years, Henan has had outstanding success in guarding against damage from hot dry winds. Recently the correspondents visited the famed national wheat expert and deputy chairman of the Henan Provincial Agricultural Commission, Liu Yingxiang [0491 2019 4382], and asked him to talk about his experiences in guarding against hot dry winds.

Question: How has Henan guarded against hot dry winds in recent years?

Answer: Large scale protection against hot dry winds in Henan is something that has come about during the past 2 years. In 1980, 31 counties and municipalities in the province sprayed an 8 million mu area with potassium dihydrogen phosphate. Results were very good in most areas and yields increased in general more than 8 percent. This year the Henan Provincial Government is preparing to invest 1.7 million yuan for the spraying of 21 million mu.

Question: Does spraying with potassium dihydrogen phosphate increase production costs?

Answer: Experiments and demonstrations in Henan Province during the past 2 years show that spraying with potassium dihydrogen phosphate or petroleum growth booster takes about 3 liang per mu at a cost of 0.40 yuan. Airplane gas costs another 0.70 yuan, so the total cost is about 1.10 yuan per mu.

Question: At what time does spraying produce best results?

Answer: The right time for spraying potassium dihydrogen phosphate is from the jointing to the booting stage in wheat, the booting stage being the best time. The right time for spraying petroleum growth booster is from the spiking to the beginning of the in-the-milk stage for wheat.

Question: Can spraying be done by hand?

Answer: Yes; either by hand or with machines (such as a mister). Both achieve the same protective results. Aircraft spraying, hand spraying and machine spraying can all be used in combination. For hillsides and small patches of land, hand spraying is exceptionally convenient; for large wheatfield areas, aerial spraying has to be done in order to finish it quickly and at the right time.

Question: How many times should spraying be done?

Answer: Two years of experience in Henan showed more apparent results when spraying was done twice rather than once. Last year Changge County sprayed once with potassium dihydrogen phosphate when the wheat was jointing, and sprayed again with petroleum growth booster when it was in the milk. As a result, the per thousand weight of grains increased by 3.52 grams and yield increased by 49 jin per mu, 20 jin more than from a single spraying alone.

In intermediate and low yield wheat growing areas, the addition of 1 to 1.5 jin of urea per mu to the potassium dihydrogen phosphate at the time spraying is done can further increase yields per unit of area. A survey performed at six sites in Xihua County showed an average 12 percent yield increase when spraying was done with potassium dihydrogen phosphate and urea, but only a 6.3 percent yield increase when spraying was done with potassium dihydrogen phosphate alone.

BRIEFS

WHEAT HARVEST--Zhengzhou, 5 Jun (Xinhua)--Various places in the northern and central parts of Henan province suffered from serious droughts last winter and this spring. Non or low wheat-yielding areas have reached more than 13 million mu in the province as Xinxiang and Xuchang prefectures are still suffering from serious droughts. Through efforts made to combat droughts and improve scientific farming, medium or high wheat-yielding areas are expected to increase from the past 30 million mu to nearly 50 million mu. The province expects to reap a bumper harvest of wheat as the area planted to wheat has increased by 5 million mu. The per mu output is expected to exceed 600 jin in Shenqiu county and the total wheat output in Dengxian county, which has a total wheat-planted area of 1.5 million mu and whose total output increased by 120 million jin in 1981, is expected to increase wheat output by over 100 million jin this year. [Text] [OW061329 Beijing XINHUA Domestic Service in Chinese 0037 GMT 5 Jun 82 OW]

PIG, EGG PROCUREMENT--The Henan provincial government recently decided that, beginning from this year, the province must implement the policy on the assigned procurement of pigs and fresh eggs. The policy provides that the number of pigs and fresh eggs for assigned procurement, which has been fixed by all prefectures and municipalities, will remain unchanged for 3 years. The tasks of the assigned procurement and selling of pigs and fresh eggs to the state must be included in the state plan for agricultural production just as the tasks of the assigned procurement of grain, cotton and oil is included in the state plan for agricultural production. [Text] [OW061329 Zhengzhou Henan Provincial Service in Mandarin 1130 GMT 9 Jun 82 HK]

DENG COUNTY WHEAT PRODUCTION--Zhengzhou, 20 Jun (XINHUA)--Deng County, Henan, has continuously increased its wheat output by more than 100 million jin for 2 years running. This year, the county's total wheat output on its 1.5 million mu of wheat fields exceeded 600 million jin for the first time. In former years, the county's per-mu wheat yield was only about 200 jin. Last year, its per-mu wheat yield reached 317 jin, while total output was 475 million jin. This year's per-mu yield is around 400 jin. NATURAL DISASTERS--From the end of April to the beginning of May, some 370 brigades in 59 communes in the 7 counties of Yongxing, Zixing, Guiyang, Leiyang, Jiahe, Rucheng and Yizhang, in Chenzhou prefecture were struck by torrential rain, hailstorms and strong winds, which caused serious difficulties for production and people's livelihood in the localities. After the natural disasters, leaders at all levels in the prefecture went into stricken areas to organize the masses to fight natural disasters and step up relief work. Chenzhou administrative commissioner's office appropriated 400,000 yuan from local finance as relief funds and 100,000 yuan as water conservation funds and supported victims with 600,000 jin of chemical fertilizers and agricultural chemicals and some 15 million jin of grain which was produced by these places and sold back by the state. Over the past few days, the prefecture has sent some 200,000 laborers every day to help with farming. Early and midseason rice on some 43,000 mu in Guiyang county was damaged and early and midseason rice on some 38,000 mu was recultivated. SIPING PREFECTURE COMBATS DROUGHT

SK080414 Changchun Jilin Provincial Service in Mandarin 2200 GMT 7 Jun 82

[Excerpts] According to our commentators (Peng Wangui and Zheng Xiemin), CCP committees and people's governments at all levels in Siping prefecture have actively led cadres and the masses to launch a struggle of combatting drought and ensuring the growth of crop seedlings. At present, except for some areas where crop seedlings have failed to sprout from the ground due to serious drought, 80 percent of all fields have a full stand of crop shoots. Transplanting of paddy seedlings has finished basically. All crop seeds sown before 28 May have become seedlings and those replanted in the late stage also began to come up.

Since the beginning of spring this year, most areas in Siping prefecture have experienced less rain than usual. Some communes and brigades have had no heavy rain for over 60 days and thus are suffering from a serious drought seldom seen for many years. Under such a situation, CCP committees and people people's governments at all levels in Siping prefecture have actively led cadres and the masses to struggle against drought to ensure a good growth of crop seedlings instead of waiting for rain and being afraid of difficulties.

Principle leading comrades of the prefectural CCP committee and the prefectural administrative office as well as leading comrades of various municipalities and counties have personally gone down to communes and brigades stricken by serious drought to take the lead in antidrought work. Yitong, Huaide and Dongfeng counties and Liaoyuan municipality have transferred some 350 cadres from county-level organs to launch antidrought struggle in disaster communes and brigades. Now more than 200,000 people in the prefecture have plunged into antidrought work and replanting of crop seedlings. In the course of drought combatting, the prefectural CCP committee also educates cadres and the masses not to be disheartened because of the serious drought and to firmly foster the thinking of striving for a good harvest by combatting drought. [passage omitted]

The signs of drought continue to develop in Siping prefecture. However, the numerous cadres and masses are more enthusiastic in combatting drought to ensure the growth of crop seedlings. At the same time, they are taking precautions against the possible waterloggings in the late farming stage.

BRIEFS

RICE REPLANTING--Taking advantage of timely rainfall from 30 May to 1 June, Dongfeng county of Jilin province organized all people including students to replant paddy rice seedlings. Some 97 percent of the paddy rice transplanting plan has been completed thanks to this crash program. [Text] [Changchun Jilin Provincial Service in Mandarin 2200 GMT 4 Jun 82 SK]

RICE TRANSPLANTING--Hailong county, whose rice acreage is relatively large in Jilin province, has summed up past lessons and basically completed rice seedling transplanting on over 300,000 mu of paddy fields in its 24 communes. [Text] [Changchun Jilin Provincial Service in Mandarin 1100 GMT 4 Jun 82 SK]

CHANGCHUN AREA DROUGHT--Commune members in Changchun area have seized the opportune time to replant crops on drought-stricken farmland. As of 24 May, some 37 communes and 1.46 million mu of farmland were hit by drought. To combat drought, the Changchun municipal CCP Committee recently held an emergency telephone conference to discuss measures to combat drought. [Text] [SK052214 Changchun Jilin Provincial Service in Mandarin 1100 GMT 4 Jun 82 SK]

PADDY TRANSPLANTING--Helong county, Jilin province, has basically finished paddy rice transplanting. As of 2 June, the county had transplanted 130,000 mu of paddyfields. [Text] [SK040735 Changchun Jilin Provincial Service in Mandarin 1100 GMT 3 Jun 82 SK]

CHANGCHUN SUBURBAN DROUGHT--Since a snowfall on 18 March, Changchun's suburban area has had no rain for 85 days. Two-thirds of the area's 131 reservoirs and ponds have dried up. The water level of potable water wells has dropped 1 meter. Over 20 production teams in the area have a drinking water problem. To combat drought, over 53,000 people, 2,500 animal-drawn vehicles and 600 motor-driven vehicles are out each day to deliver water and irrigate vegetable fields. As a result of commune members' efforts, some 109,500 mu of spring vegetables have been revived, and 26,780 mu of summer vegetable will survive. EXPERIMENTS IN DENSITY PLANTING OF CORN DESCRIBED

Changchun NONGCUN KEXUE SHIYAN [RURAL SCIENTIFIC EXPERIMENTS] in Chinese No 1, 1982 p 20

[Article by Cong Wanda [0654 8001 6671] of the Nongan Science Committee: "Preliminary Report on the Experiments in Density and Structure of the Corn Colony"]

[Text] Different forms of planting require different planting densities. The same form of planting will produce greatly different yields if the planting density is different.

To understand the rational density and the structure of the colony of corn in conditions of small proportional interplanting, I conducted field experiments at the Third Production Team of Yumin Brigade, Xinyang Commune, in Nongan County in recent years. The variety of corn for testing was ji dan 101. The form of planting was 4.2 interplanting of corn and soybeans. The planting densities of corn were two plants every 2 chi, a single plant every 1 chi, two plants every 1 chi and a single plant every half chi. For the first two forms of planting, 3,000 seedlings were preserved per mu. For the last two forms of planting, 6,000 seedlings were preserved per mu.

Results of the experiments showed that in small proportional interplanting, the yield increased as the density increased in fields with 3,000 to 6,000 preserved seedlings per mu. Although the growth and development and the major economic characteristics of the single plants in the fields with 6,000 preserved seedlings per mu were poorer, because there were more spikes per unit area, "abundance won the victory." For example: The per-mu yield of fields of two plants planted every 1 chi was 1,248 jin, while the per-mu yield of fields of two plants planted every 2 chi was 983 jin. The former yielded 265 jin more per mu than the latter, or an increase of 26.9 percent in yield. The converse was true of the fields of single plants. As the density increased, the length of spikes, the number of grains per spike, the weight of hundred grains and the yield all showed a lessening trend. In the experiment, the per-mu yield all showed a lessening trend. In the experiment, the per-mu yield of the fields of single plants planted every 1 chi was 1,250 jin, while the yield of single plants planted every half chi was 1,012 jin. The former produced 238 jin per mu less than the latter in harvest, a reduction of 19.1 percent in yield. This was because the plants were too dense, the fields were overly closed, and aeration and light penetration were not good.

The experiments also showed that when the density was low, the yield of single plants was the highest. When the density was high, the yield of double plants was the highest. For example, in the experimental fields with 3,000 preserved seedlings, the fields with single plants planted every 1 chi produced 27.2 percent more in yield than the fields with double plants planted every 2 chi. In the fields with 6,000 preserved seedlings, fields with double plants planted every 1 chi produced 23.2 percent more in yield than the fields with single plants planted every half chi.

RESULTS OF SPARSE PLANTING OF SOYBEAN PLANTS DESCRIBED

Changchun NONGCUN KEXUE SHIYAN [RURAL SCIENTIFIC EXPERIMENTS] in Chinese No 1, 1982 p 20

[Article by Zhang Guishan [1728 6311 1472] and Hu Jiahai [5170 0502 3189] of the Dunhua County Agricultural Bureau: "Equal Distance Sparse Planting of Single Soybean Plants Produces High Yields"]

[Text] The technicians of the General Dunhua County Agricultural Techniques Popularization Station and the experimental station of the county pedigree seed farm have conducted experiments in methods of soybean cultivation at the county's pedigree seed farm for 3 consecutive years. They summarized the experience of cultivating "high yields by planting single soybean plants at equal distances, sparsely." In 1981, the "sparse planting" technique was applied on 30 mu of demonstration fields. The average per-mu yield was 366.8 jin, an increase of 13.7 percent over "dense plantings." A new way to rationally plant soybeans densely by suiting measures to local circumstances has been found.

There was a saying in the past: "To obtain 4, 5 or 6 soybean plants, one has to sow 7, 8 or 9 seeds." This wasted a lot of soybean seeds. The farming technicians followed the long-standing advice of the farmers to "thin the side stems of soybeans and trim the wheat plants" and proposed "thin planting" of soybeans aimed at correcting the ever increasing dense planting of soybeans in production over the past years. This not only conserved seeds but it also increased yields. This experiment was started in 1979. The variety "dun liang No 3" which has relatively strong branching ability was selected and planted in relatively fertile soil. After 3 years of experiments, the growth of single plants was the best and the yield was the highest compared to planting of many plants and the planting of two plants per hole. The advantages of single plants included the following: 1) Seeds were conserved. About 100 jin of soybean seeds could be conserved per hectare, equivalent to a reduction of 34.50 yuan in production cost; 2) The "Thin planting method" improved the environment of cultivation. The single plants could fully absorb the nutrients in the soil and the individual plant was stimulated to produce more branches; 3) The structure of the colony, aeration and light penetration were improved and flowers and pods were protected. There were more beans, the beans were heavy and the yield was high. This technique is easy to carry out, it benefits field management and harvesting, and it can conserve labor. It requires careful dibbling. Two seeds should be planted in one hole, and one plant should be kept to preserve the seedlings. The workers of this farm praised the "thin planting method" after evaluating it is 1981. In 1982, they plan to popularize it over more than 200 mu, constituting half the area of soybeans of the whole farm.

BRIEFS

FRESH WATER FISHERY PLAN--The Liaoning provincial people's government recently sponsored a work conference on fresh-water fisheries. After discussions, the conference approved a resolution on the provincial goal of developing fresh-water fisheries. The plan discloses that by the end of 1985, the province will build 50,000 mu of up-to-standard fishing ponds and 20 large and medium-sized reservoirs which may provide 300,000 mu of fishing farms. The province will score a 100 percent increase in fresh-water fishing output. According to statistics, the 1981 per capita fresh-water fish consumption in our country was 2 jin 9 liang. Per capita consumption in our province was only 6 liangs. [Text] [SK040737 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 2 Jun 82 SK]

SNOWSTORM STRICKEN AREAS RETURN TO NORMAL

SK090851 Xining Qinghai Provincial Service in Mandarin 2330 GMT 8 Jun 82

[Text] The herdsmen of various nationalities in our province's snowstorm-stricken pastoral areas, after 2 months' hard work, have achieved good results in combatting disaster to protect livestock. Since the weather in these areas is getting warm at present, the grass has begun to turn green and the loss of animals has basically stopped.

According to incomplete statistics released in early June, 884,000 animals of all kinds died in the pastoral areas' six autonomous prefectures, 4.7 percent of the total number. This is less than what was expected by departments concerned.

Since the 1970's, pastoral areas in our province have experienced two heavy snowstorms. One occurred in 1975 and the other this year. Comparing the two, this year's snowstorm covered a longer area and lasted a longer period, but the loss was less than that in 1975. This year, the loss of full-grown animals equaled two-thirds of that in 1975.

The broad masses of herdsmen are now taking this opportune time to step up management in grazing and feeding in the summer season in order to enable livestock to regain weight as soon as possible.

BRIEFS

PROVINCIAL SUMMER GRAIN--Xian, 18 Jun (XINHUA)--Hanzhong and Ankang prefectures in Shaanxi, both of which suffered from serious flood and waterlogging last year, have reaped a bumper harvest of summer grain this year. Total output of Hanzhong Prefecture's 2.22 million mu is estimated to exceed 540 million jin. Total output on Ankang Prefecture's 2.7 million mu is also expected to exceed 500 million jin. SOME POINTERS GIVEN ON THE GROWING OF LUMIAN NO 1 COTTON

Taiyuan SHANXI NONGMIN BAO in Chinese 10 Apr 82 p 1

[Article by Ge Wenze [7041 2429 3419]: "Lumian No 1 Culturing Techniques"]

[Text] Lumian No 1 fine variety cotton was propagated by irradiation in 1971 by the Shandong Provincial Cotton Institute. It is characterized by compact plants, strong boll formation, a low drop off rate, early ripening, much cotton before the arrival of frost, wide adaptability, and strong resistance. In 1980 places all over the province began to introduce it to cultivation, and increased yields over wide areas were remarkable. However, because a small number of places did not understand the special properties and characteristics of fine varieties, the culturing methods they used were not right. As a result, increases in yields were not remarkable, or else only ordinary yields resulted. In order to make the most of the potential of fine varieties for increased yields, the following problems must be given attention in the process of promoting their cultivation.

Seed selection and seed treatment. About half a month before sowing, sunning of the seeds should begin. Before sunning, small half-filled seeds, broken seeds, fuzzless seeds, green seeds, seeds eaten by insects, seeds with little hair, large white seeds, and seeds that are not the same in size or appearance as the original ones should be picked out. Grains of the same size, color and shape should be chosen as seeds. Around noontime when the sun is strongest the seeds should be laid out on flat ground or on a mat for sunning and sunned for 4 to 5 days, until they crack when bitten between the teeth. One day before they are planted, the seeds should be soaked in water and a chemical solution to prevent diseases and to promote germination. The method of treatment is to use three parts boiling water to one part cold water or two parts boiling water to one part cold water to make warm water. The volume of water should be twice the volume of the seeds. The cotton seeds should be soaked in this for 13 minutes, after which they should be put into cold water. After soaking until the skin of the cotton seeds has softened and the cotyledon delaminates, they should be scooped out and piled up to let the action continue, being covered with burlap bags or straw. Usually the action need continue only for 8 to 12 hours.

Sowing the seeds. Lumian No 1 is an early maturing variety, which may be planted when soil temperature below one and one-half cun reaches about 15 degrees. This is around 20 April (in Yuncheng and Jinzhong prefectures). In saline, alkaline, and wet fields, sowing may be delayed until the end of April. Inasmuch as plant shapes of this variety are relatively compact, this variety can be planted somewhat more closely together than local varieties, but not too close together. On well manured and watered ground, they may be planted a little closer; on dry and not so fertile ground, they should be planted somewhat less closely. The specific distances between rows should be worked out in a flexible way on the basis of the average distance between rows, how well fields are cared for, and local custom. Generally an average distance between rows of less than 2 chi 3 cun and more than 1 chi 8 cun is about right. When the average distance between rows is about 2 chi, large and small rows may be planted, a difference of 7 to 8 cun between large and small rows being about right.

Field care. Lumian No 1 cotton tolerates fertilizer and water, has a strong boll forming characteristics, has a short boll forming period, grows weakly during the late stage and is prone to early deterioration. In tending it, speical attention must be given to the following. 1) In view of its sensitivity to water and fertilizer, it must be watered at three different times, namely watering to make the soil moist before sowing, watering during the squaring stage to promote plant growth, and watering during mid or late August for boll formation. 2) For yields of 100 jin per mu of ginned cotton, between 4,000 and 5,000 jin of mud fertilizer (base fertilizer) will be required, plus between 30 and 40 jin of ammonium sulfate (as a top dressing). One-third of the chemical fertilizer used as a top dressing is to be given during the squaring period, the other two-thirds being applied during flowering. In order to prevent premature plant deterioration, between 30 and 50 jin per mu of calcium superphosphate should be applied before sowing, and spraying done during flowering with a 2 percent concentration of calcium superphosphate extract, or a 300 to 500 part potassium dihydrogen phosphate solution. 3) Lumian No 1 cotton has few branches that do not bear cotton, and bolls are numerous in the mid and lower parts of plants. Not too many cotton bearing branches should be kept, and topping should be done early on. Generally for cotton fields that produce about 100 jin per mu, about 40,000 branches per mu should be retained. During the late season, old leaves should not be removed.

1981 PER-CAPITA INCOME FOR PEASANTS REGISTERS INCREASE

Taiyuan SHANXI RIBAO in Chinese 3 Apr 82 p 2

[Article by Zhang Zhiyu [1728 0037 1946]: "Shanxi Province Reports 1981 Rural Area Distributed Income"]

[Text] According to recently tabulated information, last year there were 22 counties (districts or municipalities) in Shanxi Province in which the per-capita income distributed by collectives exceeded 100 yuan. Nanjiao District of Datong Municipality claimed the highest per-capita income, 211.6 yuan, while residents in Nanjiao District of Taiyuan Municipality and on the outskirts of Yangqu Municipality claimed a per-capita income of a little over 200 yuan. There were 53 communes, or 11 more than in 1980, which claimed a per-capita income of over 200 yuan, and 314 brigades, or 110 more than in 1980, in which the per-capita income exceeded 300 yuan. Two brigades, Dalupo and Shangzhangjiawen had the highest per-capita income of over 1,000 yuan. Shangzhangjiawen had the highest per-capita income, 1,208.3 yuan. Long poverty-stricken Baode County registered an increase of 50.7 and 39 percent respectively in the gross output of food grains and income the levels of 1980, despite natural disasters. In 1981, each person in Xingxian County received 508 jin of food grains from collectives, the highest ever in the province. In 1978, there were only 91 economic accounting units in Jinzhong Prefecture with per-capita income exceeding 150 yuan. But in 1981, the prefecture had 1,328 such units or 13.5 times greater.

Last year, the grassroots economic accounting units throughout the province spent a total of 1,088,210,000 billion yuan in outlay on various operations, down 11.5 percent from the level of 1980, which means an additional income of 7 yuan per person in the province's rural population. In 1980, the economic return on each 100 yuan invested by communes and brigades was 270 yuan. In 1981, this economic return increased by 14.6 yuan to 284.6 yuan. In 1980, the economic return on each 100 yuan invested by Luliang Prefecture were 258 yuan. In 1981, this economic return increased by 25 yuan to 283 yuan.

This increased production and reduced expenditure have brought additional income to the state. Last year, rural Shanxi delivered 130.88 million yuan in taxes to the state, up 12.1 percent from the level of the previous year, which meant an additional per-capita contribution of 0.69 yuan to the revenue. Last Year, the province sold and delivered to the state a total of 1,756,000,000 billion jin of food grains, which represented an increase of 37.94 million jin or 2.2 percent over the level of the previous year.

NEW COTTON VARIETY GIVEN HIGH MARKS

Taiyuan SHANXI NONGMIN BAO in Chinese 10 Apr 82 p 1

[Article by Hao Tyolan [6787 7474 5695] station advisor: "New Cotton Variety, Jinmian No 5"]

[Text] New cotton variety Jinmian No 5 was systematically bred from 68-148 cotton variety by the economic Crop Institute (located at Nanhuan in Fenyang County) of the Shanxi Academy of Agricultural Sciences. This variety's output is relatively high and relatively consistent. During the 3-year period from 1979 to 1981, regional experiments conducted by 23 communes and brigades produced yields of ginned cotton averaging 125.2 jin per mu, a 10.3 percent greater yield than that from control variety Heishanmian No 1. Unginned cotton yields were 8.9 percent greater than from the control variety, and cotton yields before frost were 14.6 percent greater. Production demonstrations over the 3-year period brought yields averaging 158.9 jin per mu of ginned cotton. As compared with the variety promoted, this was a 20.7 jin yield increase, and 21.2 percent more cotton before frost. The principal characteristics of the new Jinmian No 5 variety are: greater and consistent yields, early ripening with large bolls, fairly high ginning outturn, fairly long fibers, ability to withstand yellow dwarfing and wilting, and fairly strong adaptability. Seven consecutive years of testing and demonstrations have shown an average 14.6 percent increase in ginned cotton output with individual bolls weighing 4.4 and 5.4 grams. The ginning outturn rate was from 38.1 to 39.7 percent, and fiber length measured 28.1 millimeters.

Growing of Jinmian No 5 new variety requires sufficient basic fertilization, proper close planting, prompt topping, a seedling density of between 8,000 and 10,000 plants per mu, and each plant retaining 6 or 7 cotton producing branches. In the overall field care process, early and deep cultivating must be done during the [squaring] stage to strengthen seedlings so as to derive fullest potential for a bumper harvest of large and numerous cotton bolls. During the late stage, early deterioration of plants is to be guarded against.

New variety Jinmian No 5 takes 148 days from sowing until boll opening. Its growing season is comparatively short, and its yields have been shown to be comparatively good, making it suitable for extension to cultivation in wetland and flatland drylands in the particularly early ripening cotton growing areas of Jinzhong Luliang and Taiyuan in Shanxi Province.

MEASURES TAKEN TO INCREASE COTTON PRODUCTION DESCRIBED

Yuncheng Prefecture Efforts

Taiyuan SHANXI RIBAO in Chinese 18 Mar 82 p 1

[Article by SHANXI RIBAO correspondent: "Yuncheng, Linfen Prefectures Popularize Shandong's Cotton Production Experiences"]

[Text] Since the beginning of this year, Yuncheng Prefecture has displayed determination to fight a battle in order to double its cotton output, and has adopted five specific measures for this purpose.

1. It is necessary to implement policy. Since the Shanxi Provincial Cotton Production Conference, the Yuncheng prefectural party committee and various counties under Yuncheng Prefecture have promptly sent personnel to basic levels so that they can convey policy approved by the party Central Committee and the Shanxi provincial party committee on cotton production to peasant households for implementation. Some 100,000 copies of the document on the minutes of the Shanxi Provincial Cotton Production Conference have been printed by the Yuncheng prefectural party committee for distribution to the grassroots units so that the nine policy decisions by the Shanxi provincial party committee on the development of cotton production can be quickly made known to the cotton peasants. This action has proved instrumental in boosting the morale of the peasants for cotton production this year.

2. It is necessary to implement the plans. This year, the target set by the state for Yuncheng Prefecture is to grow cotton on 2 million mu of land. As a result of repeated efforts, the prefecture has achieved success in planting cotton on 2.161 million mu of winter fallow land and of multiple cropping land, or 161,000 mu more than planned by the state, thus smashing the record of any previous year since 1958.

3. It is necessary to strengthen leadership. In order to strengthen leadership over cotton production, principal leading cadres from prefectural to county levels have begun to assume a direct role in cotton production. The prefecture now has 195 cotton-growing communes whose deputy secretaries or vice chairmen have taken the initiative to include technicians on the staff of commune-operated agricultural techniques promotion stations and to have skilled cotton growers employed by production teams join the leading groups concerned with cotton production.

4. It is necessary to apply technology. Yuncheng Prefecture and various counties have formed their respective cotton cultivation technical advisory groups (composed of leading cadres, scientific and technical personnel, and model cotton cultivators) with the aim of combining the application of traditional cotton cultivation experiences and modern science and technology in cotton production. Since their establishment the cotton cultivation advisory groups have started a technical training program. So far, the 13 training classes held by the prefectural advisory group in various counties have graduated some 2,500 students, including county and commune level leading cadres and technicians on the staff of commune-operated agricultural stations. The prefecture plans to train a total of 300,000 technicians, or one for every two households on the average.

5. It is necessary to make farming preperation. The prefecture now has 1.93 million mu of winter fallow land planted with cotton. Of this figure, some 820,000 mu of land have been set aside as cotton land to be irrigated. Since the beginning of this spring, some 320,000 mu, or 40 percent of the total, have received irrigation waters. Meanwhile, some 7 million carts of farm manure have been collected and prepared for use. This amount of manure is sufficient to provide each mu of land with 3 and 1/2 carts of manure. For the time being, some 60 percent of this amount of manure has been made available to cotton fields; cotton fields throughout the prefecture have been harrowed twice; 1.1 million mu of furrowed cotton land or 57 percent of the total have been levelled. Some 37 million jin of cottonseeds--averaging 19 jin per mu of land--have been readied for distribution, while 266,000 mu of cotton land have been covered by plastic sheets.

At present, active preparations are being made by the vast numbers of cotton peasants to dry up cottonseeds, to deliver manure to fields, and to exchange their cotton-growing technical information in the determination to insure that cotton crops will be grown to capacity and well.

Cotton Production in Linfen

Taiyuan SHANXI RIBAO in Chinese 18 Mar 82 p 1

[Article by Ru Lan [1172 3482], Yong Jiang [3057 3068], Feng Ming [7685 7686] and Rong Yue [2837 6460]: "Linfen Prefecture Promotes Shandong's Cotton Growing Experiences"]

[Text] In the course of actively studying Shandong's experiences in cotton production, cotton peasants throughout Linfen Prefecture have summed up their own experiences and lessons and displayed determination to save the "bolls from falling off the plants."

Linfen Prefecture is known for its mild climate, plentiful sunlight, and fertile soil. Historically, it once led other prefectures in north China in cotton production. But over the past 10 years, its gross cotton output has been only 30 million jin a year, while in 1981 its per-mu output of cotton dropped to the lowest level for the third consecutive year. In order to reverse this trend, early this year Linfen Prefecture held a discussion meeting attended by "eight cotton experts" and technicians sent by the Shanxi Provincial Wheat Research Institute. During the meeting, experiences and lessons centering on the cause of cotton bolls falling off the plants were realistically and conscientiously summed up, and measures for increased cotton production were studied. Later, the prefecture held another meeting attended by responsible comrades of 11 cotton-growing counties and municipalities in charge of cotton production, including deputy secretaries of county party committees, deputy heads of county governments, directors of the departments of industry and agriculture, and responsible persons of bureaus of food and of agriculture, supply and marketing cooperatives, and cotton and hemp companies. The aim of the meeting was to study Shandong's experiences in increasing cotton production despite natural disasters, to discuss specific measures aimed at increasing cotton production this year, and to adopt a resolution calling for following the example of Shandong in scoring a breakthrough in cotton production. To this end, Linfen Prefecture and counties under this prefecture have spent time, before the beginning of this busy spring farming season, conveying policies of various incentives to various communes, brigades, groups, and households of commune members, and extending to them advance pay. Active efforts are also being made to select superior cotton varieties, to improve cultivation techniques, to spread fertilizer in scientific ways, and to promote strong but low-toxic insecticides.

MOVES TO INCREASE BREEDING HOGS, MEAT PRODUCTION REPORTED

Taiyuan SHANXI RIBAO in Chinese 16 Mar 82 p 2

[Article by Guo Ce [6753 4595], Gao Yongrui [7559 0516 6904], and Sun Yong [1327 0516]: "The Raising of Sows Should Be Encouraged in Many Ways"]

[Text] The decline in the output of live hogs is a matter of great economic concern that deserves our great attention and conscientious efforts to seek a solution to this problem. Bearing this problem in mind, we recently went to interview the departments concerned and the masses of peasants in Yanbei Prefecture. Their consensus is that this decline in the output of hogs can be reversed only by taking an important step to raise more sows. Yanbei Prefecture now has 359,000 hogs in stock, down 11 percent from the level of the corresponding period of 1980. Particularly noteworthy is the fact that there are now only a little over 22,000 sows in the stock of Yanbei Prefecture, or more than 39 percent less than the level of the corresponding period of 1980. Calculating on the basis that each sow can breed 10 piglets, as indicated by the current trend of development, the existing number of sows can produce only 220,000 piglets. Added to the number of hogs now in stock, the total number of hogs to be raised this year will not exceed 580,000, down 80,000 to 90,000 from the previous year's level of 660,000.

What has caused the output of hogs to drop? The main reasons are:

1. The masses are bound to suffer great losses from selling their hogs in stock whenever supply of hogs exceed demand. This has prompted them to say: "From now on, we will never try to raise hogs again."

2. When the dry spell was prolonged during last summer, the masses became panic-stricken because they could not sell their piglets. Consequently, they had to slaughter sows without authorization. The result was a 50-percent decline in the number of sows in Guangling, Hunyuan, Yingxian, Datong, and Huairen Counties in the short period of June and July 1981.

3. Since the implementation of the production responsibility system, the old policy of allowing peasants to retain a portion of their farmland as feed growing plots and part of their harvest for feed has been declared null and void by some localities. Thus, there is no distinction between those who merit commendation for raising hogs and those who deserve punishment for declining

to raise hogs, and between those who merit commendation for raising more hogs than others and those who should be scolded for raising less hogs than others. The result was a decline in the sales of piglets and a gradual reduction in the number of hogs in stock during the second half of 1981.

4. The leadership in some localities has ignored the need to raise hogs on the assumption that in the absence of government intervention, meat will still be available everywhere.

Then what steps should be taken to solve the problems caused by a lack of interest in raising hogs, and what ways should be devised to encourage people to raise sows and to promote the large-scale development of hogs?

First, we must attach importance to the raising of hogs from the ideological point of view. In addition to actively encouraging full-time breeders to raise sows, we must call on financially sound communes and brigades to raise more sows and to operate collectively owned pigpens. In order to reverse the downward trend of raising hogs, the administrative office of Yanbei Prefecture has granted 200,000 yuan in assistance to those counties, communes and brigades which are in need of sows. The rule is that anyone who raises one sow will receive 10 yuan in subsidies, and anyone who raises one boar will receive subsidies in the amount of 30 yuan. Contracts to this effect will be signed and carried out by parties concerned.

Second, the policy of awarding prizes to the sellers of piglets, the pricing policy, and the policy of allowing peasants to retain part of their harvests as feed should continue in force; no reckless attempts should be made to change the specific regulations that have been proved effective in raising hogs by various localities. In an effort to stimulate the enthusiasm of the masses for raising hogs, the Yanbei prefectural party committee has allowed each commune member to retain 15 percent of the farmland assigned to him as his private plot, and 5 percent of this plot as land to be planted with feed crops. This privilege will be forfeited if he declines to raise hogs. The policy that entitles each breeder to receive 500 jin of feed for raising one boar, 360 jin of feed for raising one sow, and 60 jin of feed for raising one meat hog--a policy that has been enforced by some localities--should also continue in force. No reckless attempts should be made to change them.

Third, plans must be worked out to protect and develop boars and sows. The ratio of breeding sows to hogs in stock should be maintained at 1 to 10, and the ratio of sows to boars should be maintained at 20 or 25 to 1 in order to insure the normal development of the hog-riasing enterprise. In an effort to speed up the development of breeding hogs, Datong County has adopted a measure to entitle each breeder to receiving 30 yuan in subsidies for raising one boar or sow, 1 to 3 yuan for raising one piglet born of a sow in his stock. These subsidies will be provided by production teams. All sows and boars in the stock of Datong County are inspected once every year so that those capable of breeding piglets can be attained and those incapable of breeding piglets can be slaughtered.

MEASURES TO CLEAR ICE CLOGGING IN YELLOW RIVER DESCRIBED

Taiyuan SHANXI RIBAO in Chinese 23 Mar 82 p 1, 4

[Article by the ice clogs clearance command of Hequ section of the Yellow River in Shanxi Province: "Groundwork Has Been Laid for Clearing Up Ice Clogging in the Yellow River"]

[Text] In a spirit of unity, army men and civilians have been working hard to complete the basic phase of a project aimed at clearing up ice clogs in the Yellow River. They are now in a state of strict combat-readiness, preparing to take all necessary emergency measures to cope with the situation that may be caused by a cascade of icy waters.

Since last December, heavy ice clogs have appeared in the main waterway of the Yellow River, causing the icy water levels to rise to a point unprecedented in history. The cascade of icy waters has inflicted serious damage on Hequ County in this province and Jungar Banner in Nei Monggol during its movement down the Yellow River past their banks. The party and government have expressed grave concern for the safety of lives and property of the masses of people in the afflicted area. Following an inspection of the area, officials sent by the Central Committee departments concerned have directed three nearby provinces--Shanxi, Shaanxi and Nei Monggol--to set up a joint ice clogs control command. The Shanxi provincial party committee and the provincial government have organized and rushed forces to Hequ County in order to get the ice clogs clearance and rescue and relief work underway.

The first phase of the emergency rescue operation set by the three-province joint ice clogs control command includes controlling waters used by the Liujiaxia Hydroelectric Power Station on the upper stream, releasing waters through the sluices of the Tianqiao Hydroelectric Power Station on the lower stream of the river, and blasting a passageway through the heavily ice clogged main waterway of the Hequ section of the Yellow River. On 21 February, a certain PLA engineering company stationed in Shanxi was ordered to move into Hequ, and supported by the local militia units, it has spent the past half-month blasting a water drainage passageway, 30 to 35 meters wide and over 1,400 meters long, through the heavily ice clogged main waterway of the Hequ section of the Yellow River. On 12 March, it completed two gap-closing projects, one in Houjiakou and the other in Xujiakou. From 15 to 16 March, a vast army of 2,000 rescue workers rushed against time to complete the construction of an engineering project aimed at protecting a bay area and three parallel dikes totalling 2.411 meters long, thus bringing the first phase of the ice clogs control and rescue operation to a successful conclusion.

Later, the command held a meeting to work out the second phase of the rescue operation, including the dispatch of a certain air force unit and two PLA artillery companies stationed in Shanxi into the area in support of the operation. From 14 to 16 March, five sorties were flown by aircraft to drop 1 ton of bombs into the ice clogs. From 15 to 17 March, test shots fired by the artillery companies from Changsha Beach all hit the proposed targets with pinpoint accuracy. At the same time, the PLA engineering corps company also claimed success in blasting a way out of the ice clogs with missiles. Two huge generators owned by the Shanxi Provincial Bureau of Water Conservancy and some searchlights in the possession of a certain air force unit have been moved into the area, thus setting the stage for combatting the cascade of icy waters to be triggered by the blasts. During the period of ice clogs clearance and rescue operation, the command tightened up its security measures by organizing the masses to evacuate temporarily from the dangerous area, while concentrating on sowing spring wheat in the area afflicted by this disaster.

SICHUAN COTTON AREA CUT IN HALF; YIELD INCREASES URGED

Chengdu SICHUAN RIBAO in Chinese 12 Mar 82 p 1

[Article by Commentator: "Strive to Increase Cotton Yield Per Unit Area"]

[Text] Strive to raise cotton yields per unit area and do all that is possible to break previous records. This is a glorious task facing the cotton-growing peasantry of all Sichuan now that the area devoted to cotton has been readjusted.

It is entirely possible to surpass the previous record of single-crop cotton output in Sichuan. This year the province's cotton area was reduced from 3.86 million mu to 1.8 million mu and the number of cotton-growing counties have fallen from 34 to 20. These 20 cotton-growing counties are the key growing areas most suited to cotton production. Historically, single-crop cotton output in most of these counties has reached or exceeded 100 jin per mu. Their cadres and masses have experience in obtaining high yields and using scientific techniques in cotton growing. Both natural conditions and technical experiences in these counties are advantageous to achieving high cotton yields. In addition, the province's readjustemnt of its economic policy on cotton planting this year will certainly further arouse the enthusiasm of the cotton growers. The current economic policy on cotton growing has paid even greater attention than in the past to the interest of the cotton growers, making cotton more profitable to them. For instance, 100 jin per mu of ginned cotton can yield a cash income of about 200 yuan, plus an award sales of over 200 jin each of grain and chemical fertilizer. This policy promotes cotton production. We should also note that the farming activities involved in cotton production are varied and complex, and are highly technical. Each production measure requires a high sense of responsibility on the part of the commune members. With the gradual perfection of the unions forms or the production responsibility system and the carrying out of responsibility systems linking technology to output, the sense of responsibility of the cotton growing peasants and technical personnel to do well in production has risen greatly. This has helped strengthen cotton field management and enabled effective measures purported for improving cotton yields and quality to be actually implemented. The role of science and technology has been brought into full play in increasing yields. We should analyze the conditions of cotton production in a correct manner and take full cognizance of beneficial aspects while at the same time making an adequate appraisal of the threat of natural disasters and of practical problems existing in our work. Based on this knowledge, we should wrest bumper harvests from the jaws of natural disaster, promote beneficial conditions, overcome unfavorable elements and try in every way possible to boost our province's cotton production.

At present, we must seriously publicize the economic policies for planting cotton, thoroughly arouse the enthusiasm of the masses for planting cotton and, under the direction of the state plan, rapidly carry out the post-readjustment cotton field planting plans and grow good, healthy cotton. We must further stabilize and perfect the various forms of responsibility system which are suited to cotton production. Production responsibility systems are the reliable guarantees that will raise the commune members' sense of responsibility and consciousness to do a good job of growing cotton. Effective cotton production responsibility systems at present, all premised on the unified management by the production brigade, are all carried out in the forms of fixing output quotas based on work teams, specialized task teams, individual laborers or households, or the large-scale assignment of responsibilities. The essence of these systems is to take the collective ownership of land and other principal means of production as basis and carry out collective distribution of within-output quota items while leaving anything outside or beyond the quota as commune member income. This kind of production responsibility system, which simultaneously looks out for the interests of the state, the collective and the individual, corresponds to the present level of development of productive forces in the rural areas and is beneficial to the development of cotton production. Based on the wishes of the commune members, the various localities must help the communes and brigades rapidly to implement different forms of production responsibility systems according to differing production conditions and, in the course of practice, to perfect them gradually. No matter which system is adopted, it should take into consideration the characteristics of cotton, that its production is technically sophisticated, it is prone to disease and insects and its seed production is relatively complex. The system should therefore keep under unified control that which is suited to unified control and contract out whatever is appropriate. Work such as breeding seeds through hybrid cotton and controlling disease and pests must continue to be done by means of specialized contracts so as to keep these endeavors under unified control. In some communes and brigades where the area devoted to cotton growing is small and where cotton planting techniques have not been popularized, we must continue to avoid contracting cotton responsibility land to commune members who do not have the knowhow, and carry out unified management and specialized contracting. This will be more beneficial to developing cotton production.

After the problem of the relevant economic policies has been basically solved and the enthusiasm of the cotton growers whipped up, we should make the popularization of scientific cotton growing techniques an important item on our daily agenda. We must help the commune members to grasp and utilize conventional cotton growing techniques. These techniques are the basis for achieving high cotton output. If they are mastered and put into practice, it is possible to have a cotton yield of 100 jin per mu. This has been proven by many years of scientific experiment and production experience. Within a county, no matter what kind of year it is, there is always a group of communes and brigades or plots where the yield of ginned cotton exceeds 100 jin per mu. Furthermore, the vast majority of the existing cotton growing communes and brigades have all had yields equal to or exceeding 100 jin per mu at one time or another. We could say that the techniques for producing 100 jin per mu of cotton are well developed in our province. The key is to correctly grasp and apply these experiences, so that they can be implemented. It is the responsibility of the agricultural departments to adopt various measures to repidly spread conventional cotton-growing technology to all the households.

We must continue to carry out responsibility systems linking output to techniques and increase the high-yield demonstrations. Last year, some science and technology units and agricultural administrative departments signed contracts linking output to cotton-producing techniques with the communes and brigades and achieved quite good results in developing technical services. The agricultural departments of each cotton-producing district must further organize its forces and, in close cooperation with relevant scientific committees and science associations, promote responsibility systems linking output to techniques. To provide technical services through contracts, and to combine the efforts of linking output to techniques and high-yield demonstrations, plays a role in promoting large-area productions.

Cotton production is a weak link in Sichuan's agricultural production. In the last 3 years in particular, cotton output has declined continuously and the contradiction between supply and demand has become rather pronounced, affecting not only military needs and civilian uses but also the economic income of the state, collective and individuals. The leaders at various levels in the cotton districts definitely cannot consider that since the area of cotton fields has been reduced, their burden has been lightened, so that they can relax their leadership. Quite the contrary, they must exert the utmost resolve and make maximum efforts to raise single-crop cotton yields. Leading comrades at the prefectural and county levels in the cotton-producing districts must divide up the labor for cotton production. The expertise of the scientists, technicians and popularization personnel who are engaged in cotton production should be brought into full play. We must strive to raise the scientific level of growing cotton in order to promote the continuous increase in single-crop cotton yields.

I. GENERAL INFORMATION

INTERVIEW WITH STATE COUNCIL OFFICIAL ON DROUGHT SITUATION

Beijing ZHONGGUO NONGMIN BAO in Chinese 21 Mar 82 p 1

[Interview with official of State Council's Drought Combating Office by ZHONGGUO NONGMIN BAO correspondent: "Heighten Our Spirits; Vigorously Strengthen the Combating of Drought"; date and place not specified]

[Text] Question: At present, in which areas is the drought situation rather serious? What is the situation?

Answer: The area where the drought situation is still rather serious is the major winter wheat producing area in the northern part of our country, including Hebei, Shandong, Henan, Shanxi, Shaanxi, Beijing, Tianjin Liaoning, Jilin, and Inner Mongolia. Though rain and snow have recently fallen in part of that region, nevertheless the greater part of it is still dry. In the South, over most of the area there was too little precipitation in the first part of the winter, and too much in the latter part of the winter, so that only part of the region experiences drought.

In the country as a whole, the area presently experiencing drought is approximately 200 million mu, of which 70 million mu were given over to over-wintering crops, leaving over 100 million mu for which the spring unplowed land has become useless due to lack of moisture in the soil.

The characteristics of this year's drought situation are: First, owing to a long period of drought, the surface of the ground has retained little water, and the underground water level has dropped, creating serious shortage of water sources for irrigation. According to the statistics of 1 March stored water in the 58 large-size reservoirs in the five provinces and municipalities of Beijing, Tianjin, Hebei, Shandong, and Shanxi amounted to only 3.285 billion cubic meters, an average of 4.049 billion cubic meters less than it has been at this time of year for many years. Second, since last autumn precipitation has continued to be sparse, and the lack of moisture in the soil was disadvantageous for the turning green of the winter wheat or the spring plowing. Third, the wheat seedlings on unirrigated cultivated land are generally not doing as well as at the same period last year.

Question: How are the efforts to combat the drought progressing?

Answer: From the point of view of the present situation, every province and municipality afflicted by the drought has made considerable progress. Since last winter, Hebei has already completed 11,000 small-scale projects, and newly sunk or repaired 32,000 motor-pumped wells, increasing our new water sources for this spring's drought-combating efforts. The volume of extractable, channeled water in Shandong reached 11 billion cubic meters, so that it has been possible to proceed with spring irrigation, generating moisture into the spring fields, and spot planting the seeds. In Shanxi, broad areas of stored water such as reservoirs, ponds, and river channels ahve been utilized, and spring irrigation vigorously carried out. In some places in Henan where water was lacking, the masses have been active in transporting water, combating the drought, and preserving the seedlings. In Tianjin, methods were adopted of digging new rivers within rivers, canals within canals, and ditches within holes, and clearing and drying out the branch canals, so as to progress with digging up new sources of water. In the provinces of Shanxi, Henan, and Hebei the various levels of organizations assigned many cadres to the countryside to assist the communes and brigades in doing a good job of combating the drought and preserving the moisture in the soil. Moreover, fund is being withdrawn from the financial departments of local areas to support the struggle to combat the drought, and commercial departments are also in the process of finding ways to guarantee the supply of goods and materials needed for combating the drought. In some provinces and areas, 60 to 70 percent of the communes and brigades have already put into effect systems of responsibility for water conservancy, and have obtained excellent results in the struggle to combat the drought.

Question: In combating the drought, what should be stressed at present?

Answer: First, we must progress with doing a good job or ideological mobilization; strengthen our confidence in our ability to combat the drought and reap a bumper harvest; eliminate the pessimistic feeling that "since the April of this year falls on a lunar year, spring will be longer, there will be no rush to till the land" and to rely on nature for the rain; inspire enthusiasm; do a good job of managing the wheat fields; and strive hard to be able to do the spring sowing in time. Under the present circumstances of the area sown last fall and winter for food grain crops continuously getting smaller, we definitely must do everything we possibly can to overcome the difficulties and improve unit production.

Second, we must suit measures to local conditions, and do everything we can to dig new water sources. Under the present drought-combating circumstances, in order to rationally utilize underground water resources, we must place importance on the utilization of shallow-level water; have variety of wells and, in a planned way, utilize a number of types that require less labor and offer quicker results, such as earthen wells, hand pump wells, and vacuum wells. In areas lacking in water sources, we must organize the masses to haul water, and put into effect the method of digging a ditch, applying a handful of fertilizer, and throwing on a basin of water, in order to combat the drought and preserve the seedlings.

Third, we must set up sound systems of water conservancy responsibility as quickly as possible. At present, there is still a considerable portion of water convervancy measures for which systems of responsibility have not been set up, and they should be set up as soon as possible during this spring's drought combating efforts; particularly in areas where systems of contracting production and work tasks to households are being put into effect, there is all the more necessity for doing a good job of this. When in the course of putting systems of water conservancy responsibility into effect in the various areas many good examples appear we must propagandize and promulgate their good experience.

Fourth, we msut have a good grasp of utilizing water in a planned way, scientifically, and sparingly. We must, adapting measures to local conditions, popularize in areas to be irrigated the methods of apportioning water on the basis of acreage of land, charging for motor-pumped wells by the hour, the border method of irrigation, and furrow irrigation.

Fifth, for dry land, we must do well in raking and smoothing the soil in order to preserve the moisture in the soil; in areas having the proper conditions, we can put into effect the drought-combating sowing methods of planting seeds into holes, high-yield drainage ditch planting, and carrying water and dibbling in the seeds.

Sixth, the various levels of leaders should organize the various trades and professions to make a great effort to support the work of combating the drought and guarantee the timely supply of the goods and materials, money, oil, and electricity needed.

BRIEFS

FARM MACHINERY INCREASED USE--Beijing, 18 Jun (XINHUA)--More and more farm machinery has been used in China's rural areas. Total power of farm machinery in 1981 reached 210 million hp, a 7.8 percent increase over the previous year. Included are 794,000 large and medium-sized tractors and 2.05 million small tractors. The year 1981 also saw a sharp increase in peasant households' buying farm machinery. Over 392,000 peasant households throughout China were owners of tractors in 1981. [OW181405 Beijing XINHUA Domestic Service in Chinese 0023 GMT 18 Jun 82 OW]

GOAT BREEDING CENTERS--Beijing, 14 Jun (XINHUA)--China now has 157 goat breeding centers in 11 provinces and autonomous regions, each producing 100,000 skins annually, according to the Ministry of Agriculture, Animal Husbandry and Fishery. At the end of 1981, there were 78 million goats in the country, 5 million more than in 1978, the year before these centers were set up. China's commercial departments purchased 46.6 million goat skins in 1981, 6.15 million more than the previous record year of 1963. China now ranks first in the world in the export of goat skins. Exports in the last 3 years were worth 160 million U.S. Goat breeding has helped supply the domestic market with more meat, milk, wool and casings and increased the peasants' income. Delegates attending a recent national conference in Wanxian Prefecture, Sichuan Province, called for efforts to set up more goat breeding centers, and to employ scientific methods to improve goat strains. [OW181405 Beijing XINHUA in English 1230 GMT 14 Jun 82 OW]

BEIJING, JILIN SAPLING GREENHOUSES--Beijing, 15 Jun (XINHUA)--Two new large greenhouses, one in Beijing and one in Jilin Province which will produce more than four million tree saplings a year, have started production, according to the Ministry of Forestry. The Beijing greenhouse covers an area of 5,400 square meters. Chinese juniper, deodar and other coniferous trees, as well as woody plants like roses will be grown here. The Jilin greenhouse with an area of 5,440 square meters will grow Korean pine, larch and spruce saplings. The equipment was imported. China launched a massive tree-planting campaign earlier this year. In addition to these two large modern greenhouses, many simple greenhouses and nurseries have been set up to meet the needs of large-scale afforestation. There will be an estimated 370,000 hectares of tree nurseries in China by the end of this year. [Text] [OW181405 Beijing XINHUA in English 1503 GMT 15 Jun 82 OW]

WATER CONSERVATION MEASURES STEPPED UP

OW180414 Beijing XINHUA Domestic Service in Chinese 1142 GMT 17 Jun 82

[Text] Beijing, 17 Jun (XINHUA)--The peak water consumption season in Beijing this year is approaching. According to estimates made by departments concerned, while the city needs 1.55 million dun of tap water daily, only 1.3 million dun can be supplied. A responsible person of the Beijing Municipal Water Conservation Office told our reporter that the people and various units in the capital must conserve water vigorously in order to ease the water shortage.

Beijing Municipality has experienced a water shortage due to the persistent drought during the past 2 years or more. The water level in the Miyun Reservoir, which supplies water to Beijing, has dropped below the crisis level. Most of the more than 80 reservoirs in the entire city are drying up. The subterranean water level within the city limits and in suburban districts has dropped between one and two members as compared with the same period last year and about one-third of the motor-pumped wells yielded no water. The water shortage throughout the city is expected to be more serious than last year before the arrival of the rainy season this year.

Since the emergency water consumption conference for Beijing-Tianjin called by the State Council in August last year, the Beijing Municipal People's Government has called three water conservation meetings to mobilize the people and at the same time has adopted economic measures and enforced planned water consumption to change the situation of "drinking out of the same big bucket." Certain results have been achieved in water conservation. Since August last year, steps have been taken to enforce planned water consumption in groups among the 200 factories which consumed over 10,000 dun of water monthly; measures governing additional fees at progressive rates for water used in excess of the set quota were also put into effect. After these measures were put into effect, the total industrial output value of these 200 big water consumers for the first quarter of this year increased by 8.56 percent as compared with the same period of last year whereas the amount of water consumed dropped by 10.7 percent. A total of 68 units throughout the city have abolished the system of charging water fees at fixed rates, and installed water meters for over 100,000 households. In the meantime, water meters have also been installed for more than 1,500 self-providing wells [zi bei jing 5261 0271 0064] to charge fees according to the amount of water used. These self-providing wells can conserve more than 10 million dun of subterranean water.

Although some achievements have been made in conserving water in Beijing, the wastage of water in the industrial and personal sectors in the city has been serious. Although more than 94 million dun of water can be recovered for use annually from 483 factories in the city which consume over 3,000 dun of water monthly, no action has been taken so far. More than 200 units in the city still charge a fixed water fee, which causes enormous waste of water in personal use. The responsible person of the Municipal Water Conservation Office pointed out: The lack of water resources has seriously affected economic construction and the people's livelihood in the capital. It is hoped that all units concerned will adopt effective measures and do a good job in conserving water. Those units still drinking out of the same big bucket must install separate water meters for individual households and abolish the system of charging a fixed fee for water consumed.

CSO: 4007/454

PROMOTE WHEAT PRODUCTION WITH 'THREE PRINCIPLES'

Beijing ZHONGGUO NONGMIN BAO in Chinese 21 Mar 82 p 2

[Article by Yang Fengmu [2799 1409 3092], secretary of the CCP's Wanzai County Committee, Jiangxi Province: "Put into Effect the Principle of 'Three Things to Be Taken into Consideration at Once's Promote the Overall Development of Production."]

[Text] Ever since the Third Plenum of the Central Committee, on the basis of the principles of the combination of national, collective, and individual benefits, and a common growth, we have been actively engaged in a structural reorganization of agriculture, taking into account a broad view of the overall development of cropland, soil development, hillside farming, and water conservancy projects, and applying out forces to the overall development of crop farming, forestry, herding, sideline industries, and fishing. Using the figures for 1978 as a basis for comparison, though last year we met with many kinds of natural disasters, overall production of food grains still increased by 4.3 percent; total diversified economy production increased 91.8 percent; marketable grain supplied to the state increased 8.6 percent; tax revenues paid to the state increased 39.1 percent; and commune members and the collectives income distribution increased by an average per person of 102.2 percent.

Our methods, and our understanding of the situation, can be summarized in the following points:

1. Strengthen planning direction, and guide the masses to establish the concept of the situation as a whole.

After systems of production responsibility were put into effect, some people felt that it was no longer necessary to emphasize a planned economy, and a minority of places neglected planning direction. Aiming specifically at this problem, last year the county committee, in implementing the Central Committee's and the State Council's reports on actively developing a diversified economy in rural areas, educated the broad masses of cadres and the masses in the necessity of accomplishing the "three definites"; that is, definitely guarantee the completion of the state's plans; definitely pay attention to the production of food grains, and stabilize the amount of land area to be set aside for the production of food grains; and definitely expand our attention to include our hilly and mountain areas, all of our land, and our waterways, so as to guarantee the speedy development of a diversified economy. And we directed the basic levels to combine the stabilization and perfection of systems of production responsibility with the signing of economic contracts. On the basis of the state's plans and relevant policies, we conscientiously worked out the questions of land, output (output value), remuneration, costs, rewards and punishments, farm animals, and farm machinery and tools, and also solved the problems of subsidies for cadres, families of deceased war veterans and those enjoying the five guarantees, and the livelihood of families having economic difficulties. We clarified both the duties and the rights of the state, the collective, and the individual, bringing production plans down to the level of reality. We upheld the major economic position of the production brigade; had a guaranteeing effect on the completion of the state's overall procurement and assigned procurement plans for agricultural and sideline products; and effectively overcame the phenomenon in some areas of people wanting themselves and their collectives to be well off, and not worrying too much about the state's plans. Over the past few years, our county has consistently exceeded the state's overall and assigned procurement quotas for the three main items of food grains, edible oils, and pork, changing the previous situation in which certain agricultural and sideline products could not be moved or procured properly.

2. Place emphasis on economic benefits; strengthen and increase our reproductive capability.

Being concerned about economic benefits is the core problem of economic construction, and it is also an important condition for correctly dealing with the relationship of the state, the collective, and the individual. Over the past few years, the county committee has placed emphasis on taking charge of three matters: the first was establishing specialized contracts, under a system of production responsibility in which remuneration is calculated on the basis of production. Based on the needs of the different items of production produced under diversified management, we set up specialized brigades, specialized terms, specialized households, and specialized factories and, tying in the system of calculating remuneration on the basis of economic benefits produced, conscientious in doing a good job of singing the "three operas"; that is, in developing traditional products, sing the "local area opera"; in developing "top-notch" products, of singing the "expert opera"; in developing family sideline occupations, sing the "little tricks opera." We utilized the local areas' natural and labor resources to full advantage, mobilized the enthusiasm of the broad masses of commune members, and raised the labor productivity rate and the commodity rate. No 12 Production Brigade of the Huatang Brigade, Sanxing Commune selected four and a half entire labor groups to form specialized catalyst groups, and last year they earned a net profit of 18,057 yuan, averaging 4,514 yuan per person, or 4.27 times as much as the other labor groups. As for putting into effect a system of production brigades in which responsibility for work produced rests with the households, we supported the commune members in doing a good job of combined household management, and also obtained heartening results. Last year, the combined-household-managed industrial, sideline enterprises of Dai Tang Brigade, Ma Bu Commune turned over to the collective an accumulation of 10,200 yuan, enabling the collective accumulation of the entire brigade, without increasing the burden of commune members, to increase to 48.3 percent more than last year.

The second was setting up small base areas for diversified management. The small base areas were set up by the production brigades themselves on the basis of the human and material resources available, and we did not seek to enforce uniformity. By the end of last year, 2,641 small base areas for planting, breeding of aquatics, and processing were already set up throughout the county. Concerned departments provided active support with regard to granting agricultural credits, supplying material resources, and providing information and technical guidance. Jiao Hu Commune is located in a hilly area, has rich bamboo and lumber resources, and peasants with experience in paper making. Last year, the entire commune produced 9,480 dan of locally-produced paper, from which they gained a net income of over 420,000 yuan.

The third was vigorously promoting an improvement in the quality of commodities. Fireworks and firecrackers are one of our county's traditional products, and over the past few years we have vigorously promoted improved quality for our fireworks and firecrackers; "camellia fragrance" brand fireworks have for the past two consecutive years been cited as an excellent product by the department of light industry, and "repeating fire rat," "flower basket," and "airport" fireworks, and Dunbian fireworks and firecrackers were last year cited as being among the province's excellent quality products, thus increasing the product's competitive capability and expanding the products' markets.

3. Conscientiously implement [the Central Committee's] policies, and allow the peasants to receive more material benefits.

The first step is to allow the coexistence of diversified economy, various labor organizations, and many methods of calculating remuneration, without enforcing "arbitrary uniformity," and to accomplish a situation of "making change during stability; seeking good results while making change; and improving while gaining good results." The second is correctly handle the relationship between accumulation and consumption; rectifying the past "leftist" approach that "the higher the accumulation rate, the better on the one hand, preventing from happening the tendency that "the lower the accumulation rate, the better."

The distribution among commune members is partially controlled by the approximately 85 percent of the collective's gross income. The third was actively encouraging and assisting commune members in developing family sideline occupations. As for specialized households and priority households engaged in raising pigs, fish, cattle, chickens, and long-haired rabbits, they were given priority with regard to the granting of agricultural loans, feed supply, source of breeding varieties, and the prevention and cure of diseases. The fourth was implementing the Central Committee's policies on procurement, pricing, tax revenues, and rewards, allowing the collective and the individual, under the premise of completing the state's procurement tasks, to sell their surplus products freely on the open market. Thanks to the implementation of these policies, the peasants received more material benefits. In 1981, income from family sideline occupations averaged 127 yuan per person, an increase of 50 yuan over the previous year.

TREE BELTS, BARRIERS PROTECT CROPS, FARMLAND

OW280756 Beijing XINHUA in English 0716 GMT 28 Jun 82

[Text] Beijing, 28 June (XINHUA)--Twenty million hectares of farmland--one-fifth of China's total--now are protected by belts of trees and barriers of trees interplanted with crops to shelter the fields against wind and sand, according to the Institute of Forestry under the Chinese Academy of Forestry Science.

Of these, 16.67 million hectares are sheltered by tree belts, and 3.33 million hectares by trees planted alternately with crops, the institute said. Belts of young trees were planted this spring in the country's agricultural zones.

Planted in the belts are such fast-growing trees as poplar, locust, elm and matasequoia, the institute said. Interplanted with crops are paulownia, mulberry, date and persimmon trees. Fast-growing shrubby falseindigo has been planted in northern China's saline-alkali area.

According to tests, wind velocity and water evaporation in farmland protected by tree belts are reduced by 30 to 40 percent, while moisture is increased by to to 20 percent.

Tree belts now protect large tracts of farmland in China's major agricultural zones--the northeast China plain, the Yangtze River plain, the Pearl River delta and the north China plain, the institute said.

Half of farmland on the north China plain, eight million hectares, are sheltered by tree belts. Five belts in the eastern part of Henan Province total 520 kilometers in length, according to the institute.

The belts help protect crops against typhoons, dry, hot winds in early summer and cold waves in late autumn.

Under the protection of tree belts, a 3-day storm in May of 1981 caused no substantial damage to 4,300 hectares of crops in a people's commune in the eastern part of the inner Mongolia autonomous region, but it swept away 20 centimeters of surface soil of nearby farmland which had no such protection.

China's tree belts were first planted in the early 1950s on the lower reaches of the Yongding River in north China and the reclamation area in the Xinjiang

Uygur autonomous region and on the old course of the Yellow River in Henan Province, according to the institute.

In the 1960s, many people's communes built tree belts along the sides of fields, roads and ditches. These belts, which occupy little famrland, have appeared in the populous southern China and the Sichuan basin.

Every year these belts produce large quantities of timber, fuel, fruits and fodder, thus increasing peasants' income. The belts built in the 1950s have been regenerated, the institute said.

All these belts are built by peasants with state aid, it said. Forestry experts and technicians design the belts for them. To date, four national conferences have been convened to exchange and spread the experience in building tree belts.

CONTRACT DISPUTE ARBITRATION, REVISION EXPLAINED

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] in Chinese No 4, 1982 pp 31-33

[Article by Gong Zheng [7895 2973]: "Arbitration of Disputes, Changes and Revisions in Agricultural Economic Contracts"]

[Text] I. Changes and Revisions in Agricultural Economic Contracts

After a contract is signed, each signing party normally can carry out the provisions stipulated in the contract. But this is not an absolute. Agricultural production is conditioned by many factors, e.g., its long production cycle, its strong seasonal and regional nature, its dependence on natural conditions--all these things give agricultural economic contracts special features with regard to complexity, continuity and repetitiveness. When a contract is signed, although the two parties can pay attention to the above-mentioned special features, there will be changes in natural factors, and frequently no human power is able to resist natural disasters. Objectively, this causes to exist in agricultural economic contracts the possibility for change and the necessity for revision. Besides natural factors, there are some other factors that make it at times necessary to change or revise the original contract. In addition, various localities lack experience in signing contracts, and so at times it is unavoidable that there will be imperfections in the contracts. We cannot, because of stressing the strict carrying out of the contract, rigidly adhere to the terms of the original contract and not make changes or revisions. On the contrary, this would make fulfillment of the contract difficult. We retreat in order to advance; we change in order to better carry out and perfect the contract and to arouse the enthusiasm of the two parties for carrying out the contract and doing a good job in production. Practice proves that, after one of the contracting parties is hit by natural adversity, the timely readjustment of the contract quotas can strengthen the confidence of the contracting party so that he will strive hard to fulfill the readjusted quotas.

Under what conditions can a contract be changed or revised? One condition is that a contracting party has been hit by an irresistible natural calamity such as wind, hail, flood, or frost and is quite far from realizing the original quotas for output quantity or quality, and the contracting party doesn't have the power to bear the entire loss in carrying out the original contract. In this case the quotas should be readjusted. The second condition is when, because of changes of a policy nature, after the signing of a contract the prices of agricultural means of production are readjusted, so that the changes in the prices of overpurchased or discussed purchased items affect the output value and the cost contracted for. In this case, the original quotas should be readjusted. The third condition is when, during the carrying out of the original contract, it is discovered that arrangements have not been fully made, and if a readjustment is not made the fulfillment of the contract will be adversely affected. In this case, appropriate changes should also be made. In brief, readjustments and changes are to be effected under the principles that they will be of benefit to the better carrying out and fulfillment of the contract and will be of benefit in arousing the enthusiasm of the two parties for carrying out the contract.

Changes or revisions in a contract can only be effected after one party puts forward a suggestion and asks for and obtains the agreement of the other party. If for example, a production team wants to change the terms of an original contract, it must start a democratic discussion among the commune members. Contracts changed by only one of the parties, or contracts in which both parties secretly agree to make changes, are null and void. Contracts that are changed or revised must be reexamined and approved.

II. The Side That Breaks an Economic Contract Is Responsible for Making Compensation

After the contract system was put into effect, the production team's right to make independent decisions was further insured by the use of the contractual form. The economic relations between the commune and production team, between the production team and other enterprises and organizations, are linked by the contract system. Objectively, this demands that each unit that signs a contract establish a strict responsibility system and that whoever breaks the provisions and rules of the contract must be responsible for making economic compensation.

On first hearing of making economic compensation it sound as it it were a negative measure, but actually it is a positive measure. To investigate which side is responsible for making compensation when a contract is broken is a necessary condition for seeing that the supply side provides the contracted goods to the demand side and for insuring social reproduction and social consumption. A necessary condition for insuring the supply side's normal production and management is for the demand side, according to the contract, to receive the products and, in a timely fashion, to pay and fulfill its remuneration obligations. Therefore, to investigate which side is responsible for compensation supervised and promotes the better fulfillment of the contract by both sides, and spurs the contracting parties to improve management and administration, and the mutual aid and coordination between enterprises. The responsibility for compensating a breach of contract is not only an economic responsibility, but also a legal responsibility; if one side does not fulfill the contract, the other side has the right to bring suit in a people's court.

How is the responsibility for making compensation decided? A unit that breaks an economic contract and assumes responsibility for making compensation ordinarily should have made a mistake in carrying out the principle of responsibility. The mistakes include both intentional and unpremeditated mistakes.

If a unit clearly knows that its action will adversely affect the fulfillment of the contract and intentionally goes ahead and takes this action, then this is an intentional breach of contract; a unit should foresee that its action could adversely affect the fulfillment of the contract, because to neglect the main idea and not foresee this, or to foresee this but not take measures, is an unpremeditated breach of contract. For both intentional and unpremeditated breaches of contract, there is normally a responsibility to make compensation. If the contract was broken because both sides committed errors in making the contract, then both sides should separately bear their relevant responsibilities. Whatever side has subjectively been at fault should normally be held responsible for making compensation. If subjectively there is no fault, then usually there is no responsibility for making compensation; in this case people can only conscientiously fulfill the contract.

Based on the principle of responsibility for faults, if the contract was broken because of irresistible calamities (like flood, drought, hail, earthquakes, etc), there is an exemption from responsibility for making economic compensation. When, because of a fault in work by a leadership organization there is a change in plans that cause an enterprise to break a contract, the enterprise should not be held responsible. Instead, the leadership organization or the department in charge of the work should be held responsible. That some enterprises break contracts is not because they themselves are at fault but because a third party breaks the contract. For example, B does not supply to A the complete output stipulated in the contract because C did not complete its responsibilities for field management under the terms of the contract and caused a reduction in output. In this case, B should compensate A for the latter's losses, and at the same time B has the right to recover its losses from C, so that in the end the responsibility for making compensation falls on C, which was at fault. This way of doing things is advantageous for the strengthening of the responsibility system between units and between the unit and the individual, and avoids a mutual shifting of responsibility.

III. The Mediation and Arbitration of Contract Disputes

Mediation and arbitration of contract disputes are important parts of contract management. If a dispute arises in the course of carrying out a contract the two contracting parties should take the initiative to hold discussions in order to strive as far as possible for a rational solution. If the discussions don't work, any side may, according to the limits of the authority controlled by the contract, request mediation and arbitration by the industrial and commercial administrative and managerial department in the county where the other side is located or at the district level of large or medium-sized cities. At present, the mediation and arbitration of economic contracts within the agricultural system still does not have clearly stipulated administrative organizations and arbitration procedures. Ordinarily the higher level professional department where the other side is located can be asked to mediate and arbitrate. With regard to contract disputes, our country practices a method of two-level arbitration: responsible for arbitration at the first level are the industrial-commercial administration bureaus in counties (cities) and in districts of municipalities directly under the province; responsible for second-level arbitration are the industrial-commercial administration bureaus in municipalities directly under the province, in prefectures, and in municipalities directly under the central government. Industrial-commercial administration offices can mediate but do not have the task of arbitrating. But the mediation document and the arbitration decision document have equal force. If a side refuses to obey the arbitration decision, it has, beginning with the day after it receives the arbitration notice, 10 days to appeal to the next higher-level organization that supervises contracts for a reconsideration of the decision, and this is the second-level arbitration. If it still refuses to obey the reconsidered arbitration decision, it has, beginning with the day after it received the reconsidered arbitration (second-level arbitration) decision notice, 15 days to bring the case to a people's court. If the time limit for appealing the decision or taking it to court is exceeded, and the side still refuses to carry out the arbitration decision, the bank should, according to arbitration notice, transfer the payments or compensation money that the contract-breaking unit is required to pay from the unit's account. When the contract dispute is being dealt with, if it is discovered on investigation that a person or act is criminally actionable, the contract-supervision organization will refer the case to a people's court for trial. The time period within which a mediation or arbitration can be appealed is usually set as within 1 year from the day the party has the right to appeal, and when the time limit is exceeded the party loses the right to appeal.

TYPHOON NO 5--The Central Meteorological Observatory issued a typhoon report at 1800 [1000 GMT] today: This year's typhoon No 5 was spawned at 1400 [0600 GMT] today about 320 kilometers southeast of Hainan Island, China, 17.8 degrees north latitude and 113.2 degrees east longitude. Maximum wind force near the center of the typhoon ranges from force 8 to 9. It is estimated that the center of the typhoon will move slowly in a northwesterly direction gradually approaching the coastal area of western Guangdong. Areas affected by the typhoon are: Tonight and tomorrow, in the northwestern part of the South China Sea, the Beibu Gulf, the coastal areas of western Guangdong and Hainan Island, the wind force will gradually increase to force 6 to 8. Areas along the path of the typhoon will experience strong winds of force 8 to 10. Heavy or torrential rains are expected in the coastal areas of western Guangdong and Hainan Island. All units concerned, please pay attention to weather forecasts by local meteorological stations. [Text] [OW281920 Beijing Domestic Service in Mandarin 1200 GMT 28 Jun 82]

NORTH CHINA PROJECT APPROVAL--Beijing, 20 Jun (XINHUA)--The North China Plains Agricultural Project, China's first agricultural construction project to be built partially with the World Bank's interest-free loan, was recently formally approved by the State Council. This project includes the harnessing of some 3 million mu of saline-alkaline land and land susceptible to waterlogging in 9 counties in Shandong, Henan and Anhui. The total amount of investment is 350 million yuan, 34 percent of which will be offered by the World Bank--the international development association--as an interest-free loan. According to the plan, the total grain output of the 9 counties can increase by 44 percent after the project is built. [Beijing XINHUA Domestic Service in Chinese 0137 GMT 20 Jun 82 OW]

ATTENTION TO INCREASE IN LIVESTOCK BREEDING URGED

Improvements Noted

Lanzhou GANSU RIBAO in Chinese 10 Apr 82 p 1

[Article by Shen Weixuan [3088 1983 5503]]

[Text] Recently the Provincial Department of Animal Husbandry convened a provincewide conference for the exchange of experiences on improved breeding of large livestock animals in Zhangjiachuan Hui Nationality Autonomous County. At this conference a group of advanced units and individuals received commendations, and this year's tasks for making improvements in the breeding of large livestock animals in the province were set.

The conference noted that once the rural villages of the province had universally instituted various forms of production responsibility systems, the broad masses of commune members urgently required adequate draft animal power to engage in agricultural production. They not only actively purchased large livestock animals but painstakingly raised the large livestock animals that were available, and gave attention to protection of dams to breed young. As a result of large scale breeding and propagation, the work of improving large livestock animals won heartening achievements. In 1981 improvement of oxen through the use of frozen semen overfulfilled plan by 39.6 percent for the province as a whole. This was a 1.8 fold increase over 1980. New progress was also made in the selective breeding of local varieties of Hepu [3109 2575] horses, white yaks, and Bactrian camels. Nevertheless development of large livestock animals for the province as a whole continued slow and was unable to meet needs for development of agricultural production. Considerable difficulties urgently in need of solution existed in the work of improving large livestock animal breeding. The main problem was a shortage of stud animals in many places and an insufficiently even distribution of existing stud animals, poor management of the raising of animals, and failure to make the most of advantages. Breeding organizations were not sufficiently well established and no complete breeding systems had been formed. The standards for improving the breeding techniques were relatively low; personnel turnover in the breeding crops was excessive, and the mating and breeding rate, conception rate, and the breeding survival rate was all relatively low. Selection of the local varieties that are to be bred, and the general inspection and authentication of the kind of stud animals had yet to be developed in an all-around way.

In order to change the aforestated situation, the conference proceeded from an exchange of experiences to discussion and confirmed this year's tasks for improving the breeding of large livestock animals in Gansu Province. It required all jurisdictions to take firmly in hand the tasks listed below, to widely launch a large livestock animal breeding competition of "the offspring from every two female parent animals" to lay a foundation for further development of large livestock.

1. Strengthen leadership and strive to build a complete large livestock breeding system. Comrades in positions of primary leadership are to personally direct action, to supervise and inspect, and to solve existing problems in concrete ways. All prefecture and county farm livestock bureaus and livestock veterinary stations are to have specialists in charge of the work of improving large livestock animal breeding. In the building a breeding organizations, the country, the collective, and individuals should all have a part, and on the basis of distribution of dams, rational distribution should be made to form a large livestock animal breeding network.

2. Large scale growing of hay to provide relatively good conditions for raising dams. In addition, vigorous promotion should be given silage feeds and mixed feeds, allowing the bringing into play of a greater role for existing hay and feed.

3. Redistribution, breeding by selection, and allocation and sufficient supply of varieties of stud animals. Stud animals used for breeding should primarily be those varieties that meet local specifications, local propagation and breeding for local use being adhered to. Prudence should be exercised in the introduction of stud animals from elsewhere, and they should be introduced only after observation and authentication. Sufficient feed management conditions should also be assured. Vigorous efforts should be made to promote artificial insemmination techniques to make full use of stud animal breeding capabilities.

4. Attention to technical training work fot the building of a stable, technically proficient breeding improvement crops.

5. Establishment of breeding responsibility systems and institution of breeding improvement tasks. Tasks, earnings, and expenditures may be set with rewards given for overfulfillment and penalties levied for underfulfillment. Either basic wage or variable wage plus bonus systems may be instituted. In addition, animal breeding households and breeding stations should be educated, and both quantities bred and fees collected should be reasonable and within bounds, increases in earnings deriving from guaranteeing conception of female animals.

Increases Urged

Lanzhou GANSU RIBAO in Chinese 11 Apr 82 p 2

[Text] Large livestock animals are presently the main source of power and of fertilizer for the agricultural production of Gansu Province. Development of large livestock animals is also a major way in which to enliven the rural economy and increase the income of the masses. After rural villages instituted agricultural production responsibility systems, the broad masses of commune members urgently demanded able-bodied men and sturdy horses for intensive and meticulous farming. Enthusiasm for the breeding of improved large livestock animals ran very high. All levels of party and government leaders as well as farming and animal husbandry units should adroitly guide action according to circumstances, help the masses, and vigorously develop large livestock animals.

Gansu covers a vast expanse of territory in which differences in ecological conditions are fairly great. When developing the work of improving propagation of large livestock animals, it is necessary to base oneself on actual local conditions, adapt general methods to local situations, and proceed on the basis of one's own strength and ability. Consequently, stud animals must be selectively bred from local breeds with local propagation and local breeding being done for local use. Prudence must be exercised in the introduction of breeds from elsewhere. Experimentation and observation must be done, and there must be dependable conditions for care, management, hay and fodder. Otherwise, not only will economic losses be created but difficulties will ensure for the work of improvement later on. When selecting breeding methods, one must also be careful to proceed from realities.

Household feeding and breeding of livestock is the traditional method of propagating livestock in the rural villages of Gansu Province. Breeders travel the countryside going from village to village. This is a convenience for the masses and meets both the level of productivity and the dispersed farming of the province's rural villages. It helps the breeding and improvement of large livestock animals. It is necessary to explain clearly to cadres and the masses that animal breeding households that contract for state and collective breeding stock are a form of specialized contracting in agricultural production responsibility systems. When individuals pool funds to buy breeding stock and carry out a breeding business, all earnings become their own, and this is as it should be. Apprehensions about the development of livestock breeding households should be eliminated, understanding rectified, and active support given them.

Qingming [around 5 April] has passed, and soon the season for breeding large livestock animals will be here. The busy season for breeding of oxen, horses, and donkeys generally lasts only 2 or 3 months. It is hoped that all jurisdictions will take opportunity to actively develop breeding work allowing dams of suitable age to become conceived in time to win further development of large livestock animals in Gansu Province

Linxia Zhou's Livestock Industry

Lanzhou GANSU RIBAO in Chinese 10 Apr 82 p 1

[Article by He Qijun [0149 0366 6874]]

[Text] Remarkable development has taken place in livestock industry production in the Linxia Hui Nationality Autonomous Zhou. Statistics show 590,190 sheep and goats in the zhou, more than 90,000 more than the all time high. Large livestock animals number 188,300. Government has given powerful support in funds for development of the livestock industry. Last year the zhou used 817,500 yuan for development of the livestock industry. Loans issued for development of the livestock industry in the zhou amounted to 3,554,000 yuan. In addition, all jurisdictions have promptly designated for the masses "three wastelands," and have mobilized the masses to use every means for the large scale growing of hay. Last year the zhou used a reasonable amount of cultivated land plus barren mountains, and wasteland slopes to grow more than 84,000 mu of hay. Farming and livestock units at all levels have adopted effective means and have devoted efforts to the scientific raising of livestock. One thing they did was actively train technical personnel. Second, they built or enlarged artificial insemination breeding sites, and third, they developed improved sheep and goats.

Attention to Livestock Breeding

Lanzhou GANSU RIBAO in Chinese 10 Apr 82 p 2

[Article by Improvement Office, Provincial Livestock Department]

[Text] The number of livestock in Gansu Province began to rise again beginning in 1979, Development occurred during 1980, and the heavy disaster year of 1981 was an all time high year for livestock in inventory, the number amounting to more than 4.12 million, a 5.2 percent increase as compared with 1980. However, common problems now are a low breeding rate, a low pregnancy rate, and a low rate of pregnancies continuing to term. Survey shows only a single young animal is produced each year per three or even four or five female animals of proper age. This state of affairs seriously impairs development of the livestock industry. In order to change this backward situation with all possible speed, vocational units everywhere should pay strict attention to the livestock breeding season and strive to accomplish the following:

Give wide-ranging propaganda to the economic significance of much breeding, many pregnancies and much survival of all kinds of livestock. A competitive campaign of "the offspring from every two female parent animals" should be launched. Were all jurisdictions able to increase to more than 50 percent the survival rate of young born from female livestock of proper age, within a year the province as a whole would increase by 500,000 to 600,000 the number of livestock born.

Deeply probe realities, investigate and study, and do an effective job of finding out the real situation about stud livestock and dams. All jurisdictions should organize a force in conjunction with this year's spring prevention work to survey and find out exactly the situation regarding breeding, pregnancies and rate of pregnancies continuing to term during the past 2 or 3 years as a proportion of the number of dams of animals of all kinds currently able to reproduce. All breeding stock should be distinguished according to specie whether studs or dams, and form of ownership, feeding, care and use should be fully ascertained for gradual authentication and issuance of certificates. Those that do not meet specifications should be eliminated in a planned way. In places having insufficient numbers of stud animals, local breeds of studs should be bred for use and effective action taken so that dams will be bred often and have many pregnancies. Stud animals should be equitably distributed; conscientious work should be done to transfer breeding stock from areas of surplus to areas of scarcity and to cull some out, with replacements made to solve problems of inadequate numbers of breeding stock. When breeding stock are contracted to households, resales at a profit or sterilization of animals for use as draft animals is to be strictly prohibited.

State owned and jointly owned breeding stations should be conscientiously operated and full use made of the role of peasant households, with no missing the season for getting breeding done. Best use should be made of traditional peasant household or jointly owned breeding stations for vigorous development, appropriate support being given them with breeding stock and funds, and technical guidance provided as well. They should be organized to travel about the countryside to do breeding on market days. Commune veterinary stations and county run breeding stations are to institute independent accounting, do specialized contracting, closely link rights, responsibilities and profits, arouse their enthusiasm and sense of responsibility about serving the masses, and adopt scientific techniques in mating local livestock animals, in artificial insemination, and in use of frozen semen for artificial insemination to raise the breeding rate for dams of proper age.

All levels of livestock veterinary stations should designate a person responsible for attention to breeding work. They should require a 70 percent breeding rate for dams of bearing age, a pregnancy rate of 80 percent, and a 90 percent young livestock survival rate. They should assure a 50 percent breeding survival rate. Breeding stations should be required to treat dams with obstetrical disorders, breeding them after the disorders have been cured. Delivery of semen at the right time should be accurately mastered and wide publicity given to scientific knowledge about fattening of animals, preserving weight and preserving pregnancies, light use of animals for draft purposes, and ways of preventing miscarriages to increase the number of pregnancies that go to term.

Timely summarization of experiences in breeding work to give impetus to breeding work. Good examples and scientific experiences that take place in peasant household or jointly owned breeding stations or at state owned breeding stations should be promptly summarized and widely publicized to give impetus to breeding work.

RECORD HIGH SUGARCANE, PEANUT ACREAGE NOTED

Guangzhou NANFANG RIBAO in Chinese 19 Apr 82 p 2

[Article: "Zhanjiang Prefecture Sets All-Time Record for Area Planted to Sugarcane and Peanuts While Not Slackening Grain Production"]

[Text] While not slackening grain production, the province's sugar and oil production base of Zhanjiang Prefecture has striven to expand its sugarcane and peanut growing area. Statistics as of 11 April show 1 million mu of sugarcane planted throughout the prefecture, more than 240,000 mu more than last year, and more than 1.2 million mu of peanuts planted, more than 50,000 mu more than last year. The growing area for the two crops has surpassed the all-time high.

Zhanjiang Prefecture has frequent natural disasters and grain production is extremely inconsistent. This plus reduction of yields from the late crop last year as a result of disasters has meant a fairly weak foundation for grain production. Consequently, when all levels of CCP committees readjusted production patterns to enlarge the sugarcane and peanut growing area, they did not slacken grain production. Prefecture plans called for a grain increase this year of 320 million jin to be obtained largely from increases in yields per unit of area and by efforts with hybrid rice. In order to do a good job in paddy rice production, ever since last winter the prefecture has trained more than 396,000 peasant scientific personnel to lay a foundation for improving rice farming techniques, and particularly hybrid rice farming techniques.

In enlarging the area planted to sugarcane and peanuts, Zhanjiang Prefecture has stressed both increases in yields per unit of area and in total output. This year all jurisdictions are fairly attentive to the promotion of advanced techniques, to scientific farming, and to increased applications of base fertilizer in an effort to get full stands of sturdy seedlings and increase yields per unit of area. Dianbai County, the famed peanut production area, convened a conference for discussion of high peanut yields during mid-January for the purpose of increasing peanut yields this year. This conference summarized and exchanged experiences and put forward six measures for high peanut yields this year. As of now this county has already planted 205,000 mu of spring peanuts, 5,000 mu more than plan. In Suiqi County where peanut production has been historically low, the County CCP Committee and County People's Government allocated 70,000 yuan of public funds to bring in from outside the county 146 peasants versed in peanut growing to provide technical guidance, one peasant versed in peanut growing for each production brigade. Now the county has planted 130,000 mu of peanuts and planting quality is everywhere better than in former years.

BRIEFS

REHABILITATION MEETING--On 5 June, the Guangdong Provincial Economic Committee held a meeting of railroad, port, sea transport, shipping, grain and fuel departments on further arranging measures for crash-transporting materials which are urgently needed to restore production and normal life in disaster areas. According to information, some 300,000 tons of coal, some 93,000 tons of wheat and some 56,000 tons of chemical fertilizers must be transported by ship through Huangpu Port and some 72,000 tons of grain must be transported by train. Representatives from various relevant departments who were present at the meeting declared that they would make concerted efforts to crash-transport materials as quickly as possible. [HK080702 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 5 Jun 82 HK]

LOW-YIELDING FARMING--At the Guangdong Provincial meeting on improving low-yielding farmland, the Provincial Agricultural Committee Chairman Du Ruizhi said that there was a bright prospect for the province's basic farmland construction and that the low-yielding farmland would be improved. Comrade Du Ruizhi summarized the province's situation of improving low-yielding farmland by saying that the masses were more interested in improving low-yielding farmland, the cadres were more capable in carrying out measures, the leaders had been attaching more importance to the task and the result was getting better and better. After visiting some advanced units, the participants have strengthened their resolution in improving the low-yielding farmland. [HK140519 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 9 Jun 82 HK]

WATER HYGIENE CONFERENCE--The Guangdong Provincial People's Government recently held a conference in Xinhui County on improving water hygiene for the rural population. The conference decided that the province would improve water hygiene for 2 million people in rural areas within this year and 8 million people in rural areas within 3 years. This was the first provincial conference which was held by the Provincial People's Government on improving water hygiene. Some 140 responsible people of all prefectures, counties and municipalities attended. Vice Governor Yang Kanghua spoke. Over the last 2 years, the province has made efforts to improve water hygiene. The province has now supplied hygienic water to 3 million people in rural areas throughout the province and some 70 percent of this water is tap water. At present, some 13 million people in rural areas in the province still use water from rivers and ponds as drinking water and 1.5 million people use water from ditches, lakes, wells and streams as drinking water. Due to unhealthy drinking water, enteric epidemic diseases occur year-round. Agricultural chemical poisoning and food poisoning occur often. The incidence of tumor increases year by year. This is a major task to which the great attention of people's governments at all levels must be drawn. The province must rely on its own efforts to improve water hygiene in rural areas. [Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 11 Jun 82 HK]

GUANGDONG PEASANTS PURCHASE TRACTORS--At present, peasant households in Guangdong Province have individually or jointly purchased some 63,000 tractors, which constitute about 40 percent of the total number of tractors used in agricultural production throughout the province. According to statistics, the total amount of work done by tractors in spring farming this year in the province was 12.4 percent more than in the corresponding period of last year. Peasant households in Huiyang prefecture have individually or jointly purchased some 11,000 hand-held tractors throughout the prefecture. From January to April this year, the province trained some 21,000 new tractor operators. [HK250709 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 22 Jun 82]

BAKING DEMONSTRATION--In order to improve quality and achieve more varieties of bread to meet the people's needs in daily life, the Guangdong Provincial Food Industry Association sponsored a technical demonstration of bread baking and invited an Australian expert (Dennis) to provide technical instructions. After repeated experiments, initial results have been achieved in improving bread production. "Yesterday morning, accompanied Guangzhou Vice Mayor Zuo Ming, First Secretary of the Guangdong Provincial CCP Committee Ren Zhongyi inspected the technical demonstration of bread baking by the Australian expert. He had a cordial conversation with research workers who attended the demonstration." Comrade Ren Zhongyi said: "Production bread which is inexpensive and good is an important work of directly serving the masses. In particular, it is a matter of significance in Guangdong to gradually increase the supply of cooked wheaten food and change the habit of eating rice alone. This will provide people with more nutrition and build up their helath. To attain this objective, we should enhance the quality of cooked wheat food and increase its variety so that the masses will like to eat it." Comrade Ren Zhongyi added: "Food processing should be geared to the needs of the society and be carried out by factories. In doing so, we can free more people from housework so that they can devote more energy to the four modernizations." [Summary] [HK220800 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 21 Jun 82]

GUANGDONG EXPORT OF LITCHI--To strengthen the management of the export of Litchi, the Guangdong provincial people's government has decided to implement a permit system for the export of Litchi from today. In accordance with this regulation, the export of Litchi in the province must be conducted by the Guangdong provincial food import and export branch company and its subordinate branch companies and no other units or individuals are allowed to conduct the export of

Litchi. Tourist departments and Litchi production places must not organize tourist activities which include eating Litchi free of charge in its production places. Units which conduct the export of Litchi must apply to the provincial foreign trade bureau in advance for an export permit. The customs can only allow the export of Litchi on the production of an export permit. This regulation is applicable to Shenzhen, Zhuhai and Shantou special economic zones. [HK211103 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 15 Jun 82]

HAINAN RUBBER PRODUCTION--With the support of people of various nationalities in Hainan Li-miao autonomous prefecture, Tongza Agricultural Reclamation Bureau has developed rubber production relatively quickly. Last year, it produced some 30,000 tons of dry rubber. In accordance with the spirit of the state council's decision on speeding up Hainan construction, the agricultural reclamation bureau recently appropriated profit retention funds of 3.18 million yuan for all counties, communes and brigades in the autonomous prefecture. MEETING ON RURAL WORK, ECONOMIC CRIME

HK120438 Guiyang Guizhou Provincial Service in Mandarin 2315 GMT 11 Jun 82

[Excerpts] According to GUIZHOU RIBAO, the Provincial CCP Committee held a conference of prefectural and municipal CCP Committee secretaries from 31 May to 8 June. The meeting concentrated on discussing the basic tasks in the next stage of rural work and the question of launching in depth the struggle against serious economic crimes. The meeting held: Since the 3d plenary session of the 11th Central Committee, the province has followed the central measures on readjusting the rural policies, acted in light of Guizhou reality, and adopted the following four main measures:

1. We have promoted various types of production responsibility system linking remuneration to output. In this way we have effectively eliminated the defect of eating out of a big pot, which existed for a long time in the collective economy, and greatly mobilized the peasants' enthusiasm.

2. We have instituted the guiding principle of actively promoting diversification without the slightest slackening of grain production, initially carried out agricultural restructuring, and promoted the development of commodity production.

3. We have reduced the excessively heavy state grain procurement quotas and raised the procurement prices for agricultural and sideline products. This has eased the peasants' burden, and they have gained real benefit.

4. We have opened up the rural trade fairs, expanded the circulation channels, and further enlivened the rural economy.

Practice has proven that the system of assigning the land to each household in exchange for fixed levies is not only an effective measure for solving the peasants' food and clothing problems but is also a new starting-point for probing the building of modernized agriculture that suits the province's reality.

The large-scale changes are now basically over. In the new situation, the task of protecting and developing the productive forces is laid before us. The basic task in the next stage of rural work should be to strengthen the party's ideological and political work in the rural areas, fully perfect the production responsibility systems, and protect and develop the agricultural productive forces. In accordance with this basic task, the meeting demanded that the party committees at all levels do a good job in the following respects:

1. Uphold the socialist orientation and fully perfect the production responsibility systems. We must grasp ideological education--the cardinal link--continue to correct the liberalization trends of small production, and enhance the socialist awareness of the cadres and masses.

2. Take steps to protect and develop the agricultural productive forces. In order to do this, it is necessary to study and map out a new strategy for promoting all-round agricultural development. In light of actual Guizhou conditions, under the premise of ensuring steady growth in grain production, we must speed up the development of diversification, promote the contract system in an all-round way and strengthen planning guidance over agriculture, vigorously popularize agricultural technology and turn science and technology into practical productive force, improve commodity circulation and further enliven the rural economy, and support poor rural units and households according to the circumstances.

3. Rectify and readjust the leadership groups at all levels and improve the combat-effectiveness of the party organizations. In order to strengthen party leadership over rural work, it is essential to work from top to bottom and carry out ideological rectification and the necessary organizational readjustment of leadership groups at and above commune-level and of brigade party branches. The rectification and readjustment of the leadership groups must be carried out in batches. It is first necessary to solve the problems of a few weak and lax leadership groups at and above commune-level and of some paralyzed and semi-paralyzed brigade leadership groups.

The meeting also pointed out: We absolutely cannot relax planned parenthood work. We must grasp the two kinds of production together and strictly control population growth.

On the struggle against serious economic crime, the meeting held: We have already achieved initial success, however, the development is uneven, and it is essential to strengthen leadership and carry out the struggle in greater depth. Judging by the facts unearthed in various places, there is rampant economic crime in Guizhou. This has done great and shocking harm to socialist construction.

The meeting held: The central decision to launch a struggle to hit at serious economic crime is extremely necessary and correct and of great significance. However, there is still resistance to launching this struggle. This is mainly because certain leadership cadres with inadequate understanding cannot see the gravity, harm and danger of illegal and criminal activities in the economic field, nor do they realize the importance of waging this struggle. Hence they are slow and ineffective in action. There are also people who have accepted the lessons of movements of the past in a negative way, harbor lingering fear, are full of misgivings, and maintain a philistine notion of "growing more flowers and less thorns." They cannot take a clear-cut stand in grasping this struggle. Some leaders are afraid of drawing the fire onto themselves due to their own involvement, and take an attitude of resisting this struggle. They even harbor criminals.

In view of this situation, the meeting put forward the following specific demands for further launching the struggle:

1. Study in depth the relevant central instructions, enhance understanding of this struggle, and change the situation of weakness and ineffectiveness. CCP committees at and above county-level must spend some time in further studying the central documents in connection with reality. They must heighten understanding and grasp the weapons.

2. Strengthen leadership. The principal leading cadres must personally concern themselves with the investigation and handling of important and major cases, and help the case workers to clear away resistance, analyze the cases, get a clear picture of their nature and handle them in an appropriate way.

3. Grasp the points of emphasis and the policies and tackle the cases well.

4. Closely coordinate actions. The party's discipline inspection departments and the government's public security, procuratorial, judicial, and industry and commerce administrative departments must promptly exchange information and look into close cooperation. They must not go their own way and push problems across the table at each other.

5. Give full play to the power of the policies.

6. Taking the struggle against serious economic crime as the cardinal link, it is necessary to strictly enforce party discipline and correct party work style. This is a most realistic and effective measure for rectifying the party and work style in present circumstances. Unhealthy trends in the party conceal economic crimes, while economic crimes promote the growth of unhealthy trends. Hence, while hitting at serious economic crimes, it is also necessary to do well in investigating and handling other serious violations of law and discipline.

HEILONGJIANG

SERIOUS DROUGHT, INSECT PESTS REPORTED

SK150517 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 14 Jun 82

[Excerpts] The Provincial People's Government held a telephone conference on the evening of 14 June to urge the people throughout the province to swing into action to deepen the struggle to combat drought, eliminate insect pests and protect seedlings so as to reap a good harvest this year. Deputy Governor Wang Caoli chaired the conference. Comrade Wang Liming, secretary of the Provincial CCP Committee and deputy governor, spoke.

Comrade Wang Luming pointed out: Soil moisture in most areas of our province is sufficient this year. During the spring sowing period, temperatures were high and seedlings emerged earlier and grew well. Since early May, however, consistent high temperatures without rain have prevailed in the province to make drought and insect pests more serious with each passing day. The drought and insect pests, which are still developing, are characterized by the serious effects they caused, the large areas they have afflicted and by their rapid development. They pose a great threat to a good harvest. So far, drought has appeared in 55 towns and counties, afflicting 37 million mu, of which 15 million mu are seriously afflicted. Grown grass borers, which are sporadic destructive insects causing comparatively great damage, have appeared in great numbers in 28 towns and counties. The areas they inflict, their density and [words indistinct] are greater than in 1980, when they caused great damage. A great number of grown armyworms have also appeared in the eastern part of our province. For this reason, to win a success in the struggle to combat drought, eliminate insects and protect seedlings have become urgent fighting tasks in our efforts to reap a good harvest and achieve 30 billion jin of grain output.

Areas where drought is serious should make full use of all water sources, such as rivers and ditches, and build makeshift pumping stations to expand irrigated areas. All pump wells should be put into operation and all water-delivery tools should be used to irrigate fields to protect and save seedlings. We should mobilize the masses to inspect the fields and replant seedlings where necessary and see to it that [words indistinct]. Management of water for paddy fields should be strengthened so that seedling transplanting and irrigation can be successfully accomplished. Paddy fields for which water supply is impossible should be changed in good time into fields of early-ripening soybeans.

NEW EMPHASIS GIVEN RAISING OF PONDFISH

Harbin HEILONGJIANG RIBAO in Chinese 17 Mar 82 p 1

[Article: "Nenjiang Prefecture Hastens Development of Fish Raising Industry. Readjusts Production Programs For Use of Natural Resources"]

[Text] Nenjiang Prefecture has readjusted its fishing industry production programs. While adhering to state ownership as the mainstay and communes and brigades as the foundation, it has provided help to individuals to raise fish, has given impetus to substantial increase in the prefecture's water surfaces used for the raising of fish, to fish output, and to quantities sold in a change away from many years of slow development in the fishing industry and losses resulting from operations.

Nenjiang Prefecture has fairly abundant aquatic product resources, which have gradually found use as a result of readjustment of policies during the past few years. Longjiang County has 120,000 mu of water surfaces for the raising of fish, only one-third of which had formerly been used. By using state, collective, and individual production channels for development of the fishing industry last year, water surfaces used for the raising of fish increased from 40,000 mu to 67,000 mu and raising of fish by commune members in the county developed from zero. In Xibaitu Production Brigade in Baishan Commune, commune member Liu Fengcai [0491 7685 2088] was given a small bit of water in the brigade last spring, which he stocked with minnows. Before the onset of winter, each fish weighed about 7 liang and he harvested a total of slightly more than 200 jin of fish. The masses said with praise, "A small fishpond is a treasure. Costs are low and earnings are high; every household can do it." The Hongsheng Commune CCP Committee in Tailai County made fish raising a major project in its economic diversification work, putting it into effect brigade by brigade. Now nine of the 13 brigades in the commune are raising fish with remarkable results. Water surfaces being used to raise fish throughout the prefecture have grown to 410,000 mu, a 17.4 percent increase over the same period last year. This includes a prime water surface raising area of more than 3,000 mu, which has increased 10 fold over the same period last year. Fish raising sites have grown to number 388, a 40 percent increase over the same period last year. Fish raising by individuals is being done at 52 sites. Fishponds have been built on more than 4,600 mu, and last year output of sheatfish totaled more than 5,300 tons, a more than 48 percent increase over the previous year. More than 10 million fingerlings were produced, a 20.6 percent increase over the previous year. Value of fish marketed was 3.77 million yuan, a 46 percent increase over the previous year for a profit of 340,000 yuan.

In order to meet needs for development of the fishing industry, Nenjiang Prefecture administrative offices and the people's government of each county ran training classes in the planned training of fish raising technicians. Since last year, the prefecture and counties have run 15 technical training classes to train more than 400 technical personnel enrolees. Prefecture and county aquatic product units also sent technical cadres to give guidance on the fishing industry throughout the year to rural communes and brigades.

WATER MANAGEMENT REPORTEDLY IMPROVES OUTPUT

Harbin HEILONGJIANG RIBAO in Chinese 21 Mar 82 p 2

[Article by Heping Irrigation Management Station, Qing'an County: "Old Irrigation District Makes New Contributions Through Scientific Management of Water"]

[Text] The province's Heping irrigation district is an old irrigation district with more than 40 years of development. The cultivated land area it serves covers 150,000 mu of which the area designed as wetlands amounts to 86,000 mu. Formerly scientific use of water was not practiced, so in 1978 almost 3,000 mu of wetlands had to delay the time when sowing was done for lack of water, and output decreased. Last year we instituted scientific use of water to assure proper irrigation of 73,000 mu of wetlands. Autumn brought a bumper harvest for an initial savoring of benefits from scientific water management.

Mid-May to Mid-June every year is the dry season in the irrigation district. In order to assure timely irrigation, we have renovated catch basin projects, and along drainage ditches we have selected places where the topography is favorable to build check gates to block drainage of water from upstream and send it downstream into ditches for use, and to drain returning water upward so it can irrigate as it comes back downward. In order to make full use of spring floods, in recent years the irrigation district has everywhere promoted early preparation of the soil, early release of water, early soaking of fields, and early sowing. Formerly the gates were opened and water released on 1 May each year, but last year the water was released on 20 April, soaking and sowing of the fields being done about 10 days ahead of time. Thus, full use was made of dry season runoff for reduction of the irrigation rate, and a saving of water was effected. Formerly a single discharge irrigated only 6,000 mu, but now it irrigates 10,000 mu. Early release of water, early soaking of fields, and early sowing also help raise soil temperature so that cumulative heat can beat cold damage. Formerly sowing was done once air temperature was steady at over 12°C, but now sowing is done when temperature is steady above 8°C. This comes 10 days earlier and provides an additional cumulative temperature of more than 100 degrees so that the full flowering of rice comes in early August before it can be interfered with by coldness. This reduces the empty glume rate and increases rice yields per unit of area.

Additionally the irrigation district has applied to production the irrigation system worked out through 7 years of experimentation, i.e. meager water for germination of sturdy seedlings, shallow water for tillering, and sunning of the fields for healthy stems. This method is known as "shallow-sunning-shallow," and it saves about one-third the water formerly used for large scale flood irrigation. Along w h the spread of "shallow-sunning-shallow" irrigation method, we promoted a method of stagnant water irrigation during the final stage of rice tillering, and flowing water irrigation after the late tillering stage, which also produced very good results. During the early stage when rice seedlings are small, the water does not flow and temperature increases faster from the sun's rays than would be the case were the water to run. Water and soil temperatures are thereby increased by an average 0.5 degrees or so. During the late stage of tillering, when rice seedling growth is vigorous and foliage has closed the rows, the rice leaves blocking out the sun's rays, water temperature in the fields is about 0.5 degrees lower than water in the irrigation ditches. This irrigation technique can, in the course of the entire period of rice development, produce 40 to 50 degrees more cululative temperature, which helps rice growth and development, advances ripening, and increases the per thousand grain weight. Following the practice of scientific water management in 1981, the actual field area irrigated was 73,000 mu, an increase of 35,000 mu over what it had been. Yields increased from the former somewhat more than 380 jin per mu to 550 jin per mu.

METHODS TO INCREASE SOYBEAN YIELDS EXPLORED

Harbin HEILONGJIANG RIBAO in Chinese 21 Mar 82 p 2

[Article by Professor Wang Jinling [3769 6855 7117], Deputy Provincial Governor: "Talk About Techniques For Increasing Soybean Yields Per Unit of Area"]

[Text] Soybeans are rich in nutrition and have a high economic value as well. Everywhere in the world soybeans will henceforth be a red hot item with broad uses and for which demand will be greater than supply. In China, following increases in prices paid for soybeans peasants stood to make an economic profit and the state needed soybeans, so a trend toward expansion of the growing area took place. Though Heilongjiang Province is the major soybean growing area of the country, its soybean output last year amounted to only slightly more than 4 billion jin. Total output was not great and yields per unit of area were not high. They were far from satisfying domestic and foreign market needs. Consequently, while suitably expanding the soybean growing area, attention should be given to increasing soybean yields per unit of area for greater soybean output.

For many years soybean yields in Heilongjiang Province have fluctuated around an average 130 to 160 jin per mu. In the low yield year of 1976, yields were only 119 jin per mu, while in 1975 yields were as high as 196 jin per mu, yields differing greatly from one region to another. These differences show that potential for increase in average yields per unit of area is great. All that is needed is further adoption of workable agrotechniques plus an increase in the level of scientific farming, and increase in average soybean yields per unit of area in the province to more than 220 jin will be entirely attainable. By and large, increase in the province's soybean yields per unit of area requires attention to the following several crucial problems.

Soil fertility is a basic problem affecting high yields of all crops. Since soybeans are not as responsive as corn, wheat, and rice to topdressing of nitrogenous fertilizer, increase in soybean yields per unit of area requires special attention to the use of organic fertilizer to build up soil fertility to promote good development of root nodules so as to make the most of the role of root nodule bacteria in fixing nitrogen. The Wuyi Brigade of Xinhau Commune in Suihua County and some units in Bayan county provide very good examples. For a long time they have continued to use barnyard manure and straw ashes to build up soil fertility, and increases in soybean yields have been consequently remarkable. In addition to applying organic fertilizer to the soybean fields, phosphate fertilizer such as calcium super-phosphate was also provided to increase the soil's phosphate content. On lightly alkaline and white bentonite soil fields, they used quick acting phosophate fertilizer such as dihydrogen phosphate for better results.

Missing seedlings and broken stems with resulting uneveness in stands is one of the major reasons for low soybean yields in the province. The main reason soybean seedlings are missing is sloppy farming, low quality of sowing, and damage to seedlings when weeding and banking of soil is done. Therefore, before sowing begins it is necessary to plow, ridge, and otherwise prepare the soil, and when soil tempteature climbs to more than 10°C, machinery should be used for on-time early sowing to take advantage of soil moisture and strictly guarantee quality of sowing to get a full stand. Careful weeding for growth of sprouts should be vigorously promoted, hand hoeing done to loosen soil around emerging shoots and to eliminate sprouting weeds, seedlings being added where needed, and soil banked around plants. In addition the experience advocated by Nahe County of "early, late and close" whereby fields were sealed off and weeds eliminated before sowing was done should be promoted through the adaptation of a general method to local situations. Alternatively, a herbicide such as fuleling may be used in advance of sowing on seedling strips.

The soybean growing areas of the province substantially have rather fine local and matched varieties suited to local conditions. The problem is that frequently there is no sensible matching of varieties on the basis of local soil fertility conditions and levels of farming. Since most of the varieties presently being extended to cultivation need high fertility while the general run of production fields frequently are unable to meet their needs for fertility, in years of scant rainfall, in particular, soybeans do not grow sufficiently vigorously and their yield potential is not fully realized. Reasons why varieties are not matched to production conditions are numerous, but problems of understanding are very crucial, while problems with work practices naturally also exist. For example, seed units should not only actively breed varieties suited to dominant production conditions, but should also promote, in combination, both fine varieties and fine farming methods. In this way results would be somewhat better.

Great differences in soybean yields occur from one year to another. This is influenced mostly by quantity of rainfall and differences in crop patterns. If dry weather occurs during August when pods and beans are forming, pods drop off and the weight per hundred beans falls, causing greatest damage to soybean yields. Second most serious is dryness during the flowering period. In order to overcome damage from dryness during the flowering, pod formation and bean formation period, in addition to watering, overly close planting is also to be avoided. During the seedling stage, field furrows should be deeply loosened and overly large beans should not be selected for planting (those larger than 22 grams) nor should those varieties be selected that do not grow vigorously or require large quantities of fertilizer and water. As the ratio of soybean planting increases, improvements in fertility and water conditions and increase in density will tend to increase the seriousness of insects that hollow out the beans, of cysticercosis, and of gray speck disease. Expansion of the sunflower growing area may also advance the spread of sclerotinia rot. Therefore, in soybean growing areas the proportion of sunflowers should not be expanded; growing areas should be dispersed, and particular care should be taken in low temperature areas.

PROVINCIAL NOTICE ISSUED ON ALL-OUT POTATO PRODUCTION

Harbin HEILONGJIANG RIBAO in Chinese 20 Apr 82 p 1

[Article: "Sufficient Growing of Potatoes According to Plan Required by Provincial Government Office Emergency Notice to All Prefectures. Provincial Commune Enterprises Bureau Requires All Commune and Brigade Enterprises To Help Implement Potato Growing Plans to Assure Raw Materials for Processing and Fulfillment of Tasks For Surrender to Higher Authority of Potato Products"]

[Text] The Provincial People's Government Office has issued an emergency notice requiring all prefectures to implement conscientiously potato growing plans.

Recently Provincial People's Government leadership comrades made a survey in Nenjiang Prefecture where they discovered that this year's potato growing plans had not been adequately implemented, the area planted continuing to decline. They required all jurisdictions to take action for earliest possible implementation at the grassroots of potato growing plans handed down by the provincial government. Major suburban production areas, and Nenjiang and Heihe prefecture potato base counties in particular, are not to reduce the growing area. There is to be continued carrying out of planned purchases, surrender of fixed quotas, and the handing down of assigned procurement quotas. All county commercial units are to sign production and marketing contracts with production teams on the basis of plans handed down by the state, and assigned procurement quotas are to be levied on production teams and households. The contract system will be used to dovetail collective and individual commune member production with state assigned procurement tasks. In every county, until such time as procurement quotas for potatoes and potato products have been fulfilled, production teams (including farms) may not sell potatoes in country fair trade or offer them for sale themselves. Counties that have fulfilled procurement quotas may market potatoes themselves or have commercial units help market them.

The notice required a good job of potato planting and of exchanges between surplus and shortage areas. Last year's potato output fell as a result of disasters, so this spring seed potatoes have been in very short supply. Commune members should be mobilized to eat fewer of them, and they may not be used as livestock feed. In addition, city and town residents should be mobilized to sell to local vegetable companies potatoes they have in storage in order to help production.

By way of implementing the aforestated emergency notice, the Provincial Commune and Brigade Enterprises Administration has required all levels of commune and brigade enterprise management units to actively cooperate with units concerned in taking in hand implementation of potato planting plans to assure sufficient raw materials for potato processing industries. Commune and brigade enterprises are to sign contracts for the supply of raw materials for processing with potato planting production teams, other teams, and households so that enterprises will be able to start work at once and maintain normal production. Commune and brigade enterprises are also to sign production and marketing contracts with procurement units to guarantee fulfillment of state quotas as well as to organize marketing of output in excess of quotas.

LIVESTOCK BREEDING HOUSEHOLDS ESTABLISHED

Harbin HEILONGJIANG RIBAO in Chinese 17 Mar 82 p 1

[Article: "Nine Households Specializing in Breeding See Results Within a Year. Suihua Prefecture Formulates Ways of Supporting Specialized Households and Requirements for Specialized Households; Then Entire Prefecture Establishes a Group of New Specialized Households"]

[Text] Last year Suihua Prefecture established nine specialized households for livestock breeding, which have functioned very well during the year to play a supplementary role in the livestock breeding system dominated by the state and the collective. Recently units concerned in the prefecture summarized this experience and are in process of spreading it throughout the prefecture.

Last year Suihua Prefecture established nine specialized households for the breeding of livestock in individual communes and brigades in farming areas, pastoral areas, and semifarming semipastoral areas, permitting them to pursue the breeding of fine varieties of livestock as their principal occupation. This method offers four advantages: One is high labor productivity rate. One example was Wanbao Commune in Zhaozhou where the work formerly done by six specialists has now been contracted to two specialized households. They are not only responsible for the commune's breeding work, but concurrently are in charge of breeding tasks in Zhaozhou Town, at Shuangfa Commune, and in some communes and brigades of Zhaoyuan County. Second is the successful pregnancy rate for breeding done by these nine specialized households which has been very high, meeting national and provincial requirements. Third is a lightening of burdens on the state and the collective. Six of the nine specialized households have themselves raised 12 stud rams, and three households have themselves raised six stud boars for a saving to the state and the collective of a total of more than 17,000 yuan of expenses for purchase of stud livestock, fodder, breeding equipment and payment of wages. Fourth is the specialized households have increased their incomes. Last year the income of these nine specialized households totaled slightly more than 10,200 yuan, a more than 6,000 yuan increase over their real income for 1980. Seven of the households had earnings of more than 1,000 yuan.

Measures formulated by Suihua Prefecture for support of households specialized breeding and requirements on specialized households included county and commune livestock unit responsibility for providing active help to them in the purchase of stud rams and boars, frozen bull semen and horse semen, designation of land on which to grow livestock feed or providing livestock feed according to the number of head of livestock being fed by specialized households, and providing a necessary breeding ground. Requirements levied on specialized breeding households included fulfillment of breeding tasks handed down by higher authority, providing services to production teams with adherence to fee standards for specific services formulated by units concerned with no arbitrary increases. Now communes and brigades throughout the prefecture have established yet another group of new households specialized in breeding.

BRIEFS

WHEAT SOWING WELL UNDERWAY--During the past several days the continuing fine weather has been turned to advantage everywhere in the province for the rush planting of wheat at a rate of 1.6 million mu per day. As of 9 April 15.56 million mu of wheat had been sown throughout the province. This amounted to more than half of the planned wheat growing area, and was 3.7 million mu more than during the same period last year. In the eastern part of the province spring waterlogging was serious this year. On all farms, teams actively rushed the sowing of wheat in icy conditions to win the initiative. In the western and northern regions, all units in wheat growing areas carefully leveled the soil and made the most of soil moisture conditions to hasten the pace of wheat in an effort to win high wheat yields. On 4-8 million mu in the province, the land was leveled and carefully harrowed in advance of sowing. Right now wheat sowing is at a peak in western and northern regions and the pace of sowing is faster than in former years. It is anticipated that by 10 April, more than 90 percent of sowing will be completed. Right now fields everywhere are again soaking wet. While rush sowing of hilly lands in wheat growing areas is underway, efforts are continuing to dissipate soil moisture through shallow turning of the soil and by breaking ridges between fields, with leveling of the land so that more waterlogged low-lying areas may be planted. Units directly subordinate to the privince have allocated seeds for late ripening wheat to farm teams where waterlogging is serious in preparation for late sowing. HEILONGJIANG DROUGHT--Songhuajiang Prefecture, Heilongjiang Province, is attending to antidrought work to ensure good growth of crop seedlings. Among the 4 million mu of farmlands which were hit by a serious droubht, 1.2 million mu have been irrigated. In May the prefecture's precipitation was 33 percent less than the corresponding period in a normal year. Since the beginning of June, its precipitation has decreased 87 percent. The average temperatures were 3 to 4 degrees higher. The prefecture has experienced 12 7-class strong winds, affecting 11 million mu of land. [SK181127 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 17 Jun 82]

HEILONGJIANG GRASS BORERS--Suihua County's 83 percent of farmland, 1.81 million mu, has been plagued by grass borers. [SK191150 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 18 Jun 82]

ZHAODONG GRASS BORERS--Since the beginning of June this year, Zhaodong County, Heilongjiang Province, has found grass borers in 25 communes. Some 500,000 mu of crops have been plagued by grass borers. Now the county-level responsible comrades, agricultural scientists and technicians are vigorously teaching and helping the peasants to control and eliminate grass borers. TECHNIQUES FOR IMPROVING WHEAT PRODUCTION ON DRY, SLOPING GROUND

Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 2, 1982 p 31

[Article by the agricultural technical station, Xia Ye Commune, Jiyuan County, Henan Province: "A Measure To Increase Wheat Production on Dry and Sloping Ground"]

[Text] In some mountainous or hilly areas where there are no water conservancy projects available, use of dry land weirs built with clods and contour ridges on sloping ground for planting agricultural crops is a measure for increasing production requiring little capital investment and giving good results. For example, at Guandi Improved Variety Farm of Xiaye Commune, the dry land weirs are 1.5 chi [1/3 meter] high and 5 chi wide, capable of yielding 470 jin of wheat per mu, as compared to 355 jin per mu for regular fields, an increase of 32 percent. As for the ridging, on the 2.5 mu of sloping land where there was no way of retaining rainwater a ridge was built every 2.5 chi on the basis of the contour a drill barrow of wheat was sown on each weir, yielding a marked increase of 50 thousand spikelets, with each spikelets having 1-2 more kernels in it, yielding 393 jin per mu, compared with a yield per mu of 284 jin for fields on which dykes were not raised, an increase of 38 percent. These pieces of land on which weirs and ridges were built, though receiving only about 50 mm of rainfall on the average, did not lose any rainwater because they were able to retain it. In this way, what were originally "fields of three escapes" (loss of water, soil and fertilizer) were changed into "fields of three retentions" (retention of water, soil, and fertilizer). If this method were popularized for dry and sloping land in mountain areas, it would be an effective measure for promoting a change from achieving low production of wheat to intermediate production of wheat.

WHEAT PROTECTION PHONE CONFERENCE HELD

HK090932 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 7 Jun 82

[Summary] "During the current wheat harvest in our province, fire accidents have been very serious. To resolutely prevent the outbreak of fire accidents during the wheat harvest, the Henan Provincial People's Government issued an extraordinarily urgent telegram on 5 June and held an urgent phone conference on the protection of wheat and the prevention of fire, which was attended by responsible comrades of all prefectures, municipalities and counties and leading members of the Wheat Protection and Fire Prevention Command. Vice Governor Cui Ldanghua and (Bai Jin), vice chairman of the Provincial Fire Prevention and Safety Committee and director of the Provincial Public Security Department, spoke at the conference."

To resolutely prevent the outbreak of fire accidents, the Provincial People's Government demanded: "Governments at all levels must regard the wheat harvest and fire prevention as a current important rural task. They must seriously implement the measures and regulations of the Provincial Fire Prevention and Safety Committee on doing well in wheat harvesting, fire prevention and safety." It also demanded: "It is necessary conduct an inspection of fire prevention in the wheat fields." Regarding those who violate the instructions of upper levels and continue to cause fire accidents to happen, it is essential to investigate and affix the responsibility of the principal leaders for the fire accidents. It is imperative to resolutely prohibit people from drying and threshing wheat on roads. No departments and individuals are allowed to run counter to the circular of the Provincial People's Government. Relevant counties and communes must quickly investigate the reason for fire accidents which have already occurred, investigate and affix the responsibility for the accidents and strictly deal with them separately according to each situation. We must resolutely strike blows at criminals who set fire to sabotage the wheat harvest.

BRIEFS

AGRICULTURAL FUNDS--Since the beginning of this year, finance departments in Henan Province have appropriated 16.87 million yuan to support agricultural production and have also helped poor counties and poor production teams develop diversification. Over the last few years, with their assistance, some 20 relatively poor counties have developed agricultural production and the income of their commune members has increased. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 3 Jun 82 HK]

SOIL IMPROVEMENT--Zhengzhou, 15 Jun (XINHUA)--The Institute of Soil and Fertilizer under the Henan Provincial Academy of Agricultural and Forestry Sciences has made major achievements in improving the soil of low-yield fields in the province since 1979. The province has over 38 million mu of low-yield fields in alkaline land, sandy land, low marshland and dry and hilly land. The area of alkaline land in Shangqiu Prefecture was 3.2 million mu, accounting for 33 percent of the total area of arable land. As a result of soil improvement and readjustment of both crops' structure and water conservancy projects, the area of alkaline land in this prefecture has been reduced by 1.8 million mu. BRIEFS

TEA PROCUREMENT--Hubei Province had procured 71,158 dan of tea by 31 May, fulfilling 26.4 percent of the state quota for tea procurement and showing a rise of 4.6 percent compared with the same period last year. Of the total procurement, 27,641 dan of red tea was procured, fulfilling 51.2 percent of the state quota, and representing a rise of 1.2 percent compared with the same period last year. The provincial tea procurement departments at all levels adopted active measures, and increased the amount of grassroots procurement networks and workers to promote tea procurement. According to statistics, 10 counties have fulfilled more than 50 percent of the tea procurement quota and 17 counties have improved tea procurement. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 10 Jun 82 HK]

PREFECTURE GRAIN--The total output of summer grain and summer oil-bearing crops of Xiaogan Prefecture in Hubei Province this year exceeded the highest output in any previous years. The total output of summer grain reached some 850 million jin, 17 percent more than last year. The total output of summer oil-bearing crops was some 700,000 dan, 26 percent more than last year. By 18 June, the prefecture and procured some 180 million jin of summer grain, 93.6 percent of the state procurement quota; and had procured some 388,000 dan of oil-bearing crops, 78.9 percent more than the procurement quota. JUTE, AMBERI HEMP, RAMIE GLUT REPORTED

Changsha SHI CHANG TIAO JIE in Chinese 5 Apr 82 p 2

[Article: "Hunan Province Jute, Amberi Hemp, and Ramie Output and Marketing Forecast"]

[Text] This year Hunan Province's supply of jute, amberi hemp, and ramie is greater than demand, so all jurisdictions should pay attention to planting plans.

Last year the province had a bumper harvest of jute, amberi hemp, and ramie. On the basis of annual production statistics, anticipated procurement of ripe jute, and amberi hemp will be 650,000 dan (of which about 613,000 dan had been purchased as of the end of January). This plus the 400,000 dan in storage from last year makes a total of 690,000 dan. Ramie procurement will run to 310,000 dan (of which 301,000 dan had been procured as of the end of January), and this plus 60,000 dan remaining in storage from last year will mean a total of 370,000 dan. Anticipated sales by the province this year of ripe jute and amberi hemp are 460,000 dan, of which 380,000 dan is for use in making textiles. Jute and amberi hemp disposed of in the market amounts to 30,000 dan, and 50,000 dan is for export. Of the 167,000 dan of ramie marketed, 130,000 dan will be used for textiles, 30,000 dan will be disposed of in markets, and 7,000 dan will be exported. In addition to normal storage, the province has on hand 200,000 dan of jute and amberi hemp and 160,000 dan of ramie for which it can find no markets. Moreover, last year saw an increase in output of jute, amberi hemp and ramie in the country as a whole, so now the quantities in storage are fairly large and sales are slack. In order to help balance development of production and sale of jute, amberi hemp, and ramie, all jurisdictions should pay attention to planting plans. In a situation in which no apparent increase in textile use or exports of jute, amberi hemp, and ramie have taken place, Hunan Province's output of these three crops should be stabilized, i.e., the growing area for jute and amberi hemp should be stabilized at 150,000 mu, and the growing area for ramie should be stabilized at the present 220,000 mu with no blind expansion. In addition, quality should be improved, a good job being done in stripping and pickling. Supply and marketing units must strictly put into effect procurement standards and price policies; actively expand markets, and do a good job of storage.

CARROT, STICK MEASURES ADOPTED FOR HOG RAISING

Yinchuan NINGXIA RIBAO in Chinese 7 Apr 82 p 3

[Article: "'Six Fixeds' To Assure Profit From Hog Raising"]

[Text] Profits from the raising of hogs last year by state farms in Hunan Province amounted to more than 4 million yuan, a 1.2 fold increase over 1981 for overfulfillment of state assigned procurement quotas and export quotas for live hogs. Their experience was practice of the "six fixeds."

The "six fixeds" are fixed quotas, fixed amounts of livestock feed, fixed survival, fixed costs, fixed remuneration, and fixed rewards and penalties.

The state farms stipulated care of a pig sty by a man and wife (a working couple) to raise somewhat more than 100 pigs, while at the same time farming 12 to 14 mu of green feed for them. Also required was an annual output of between 14,000 and 16,000 jin of live hogs and the removal from inventory of 120 fattened hogs. For each hog raised, one-tenth of a mu of land was provided for the growing of fodder, and for each jin increase in weight, three jin of feed was paid. For the hog survival rate it was required that each sow would annually produce 14 surviving shoats. The fattened hog survival rate was 95 percent and the sow survival rate was 97 percent. Wage remuneration was figured on the basis of weight increases for fattened hogs, a remuneration of from 0.08 to 0.10 yuan being paid for each jin increase in weight. This meant a general average per capita monthly wage of somewhat more than 60 yuan with maximum earnings of slightly more than 100 yuan and minimum earnings of slightly more than 40 yuan per month.

Following institution of the "six fixeds," worker sense of responsibility increased. In 1981 they suitably cut back on the amount of feed given hogs, the amount of feed per hog falling by 22.5 percent, while the number of hogs removed from inventory nd the number exported increased over 1980 by 8.7 and 4.6 percent respectively.

As a result of cutbacks in the amount of feed given the hogs, 200 feeding personnel were cut, the feed growing area was reduced by 12,000 mu, and circulating capital was reduced by 6 million yuan. They converted the land to the growing of 10,000 mu of sugarcane for an annual increase in earnings of 5 million yuan.

AREA CORRECTS MISTAKEN IDEAS ON COMMUNES

HK120325 Changsha Hunan Provincial Service in Mandarin 2310 GMT 11 Jun 82

[Text] While studying the draft of the revised constitution, (Jinrong) District of Pingjiang County has paid attention to carrying out publicity for the masses in connection with reality. The district has also cited the basic principles of the draft to solve a number of new problems that cropped up in practical life.

(Jinrong) District is a mountainous border region. After the draft of the revised constitution had been made public, a few cadres and masses had muddled ideas regarding the provision for separation of government administration from commune management. They thought that this meant abolishing the people's communes and dissolving the collective economy. Problems of sharing out collective property and selling responsibility fields and mountains even occurred in places.

On discovering these problems, the district CCP Committee first held a meeting of commune party committee secretaries to unify their understanding. They also trained 600 backbone elements at all levels. Responsible comrades of the district and the communes then led groups to more than 600 production teams to openly promulgate the draft of the revised constitution to the masses. After 20 days of lectures and discussions, the cadres and masses deepened their understanding of the four basic principles, correctly grasped the basic contents of the draft of the revised constitution, overcame the muddled thinking of certain cadres and masses, and corrected the sinister wind of sharing out collective property. The district has further stabilized and perfected the production responsibility systems and consolidated the collective economy.

RADIO ON MANAGEMENT OF COLLECTIVE ORCHARDS

HK100849 Changsha Hunan Provincial Service in Mandarin 1000 GMT 8 Jun 82

[Notes by station reporter and correspondent: "The Problem of Nobody Caring for the Commune- and Brigade-Run Collective Farms and Orchards Should Be Solved Immediately"]

[Text] On our way to Wugang County to gather material, we noted that some commune- and brigade-run collective tea farms and tangerine orchards had been laid waste and some others had been trampled by livestock in a pitiable manner. Xingguang production brigade in Chengxi commune had a collective orchard in which 7,210 sweet seedless tangerine trees were grown. Since last winter the management of most of the tangerine trees have been equally divided among the households. Thus, some tangerine trees belonging to the collective have been transplanted by some commune members in their own private plots and some have been stolen. With the loss of more than 2,000 tangerine trees, the orchard has become a grazing ground for the cows. This is really distressing.

How has it come about that the commune- and brigade-run collective farms and orchards have been damaged in such a serious manner? As we understand it, this is chiefly because some commune and brigade cadres, in implementing the production responsibility system, have paid attention only to contracts for paddy fields. They have failed to conscientiously implement the system of responsibility for specialized jobs. During the busy season of spring sowing, all the labor force was concentrated on the responsibility fields with the result that the collective farms and orchards have been left uncared for or mismanaged. Moreover, a small number of commune members erroneously hold that assigning the households full responsibility for task completion is tantamount to dividing the fields and working alone and so have taken advantage of the opportunity to privately divide, forcibly the possession of or steal the collective fruit trees.

In order to manage well the collective orchards, in addition to helping the cadres at the commune, brigade and the levels to overcome the tendency of paying partial attention to the responsibility system, what is important is to conduct education among the commune members in adhering unswervingly to the path of socialist collectivization, public ownership of land and other basic means of production and adhering unswervingly to the system of production responsibility in agriculture. It has been stated very clearly in the "Summary of the Minutes of the National Rural Work Conference" that, being socialist public accumulation and the basis for the continued development of the collective economy, the commune- and brigade-run collective farms and orchards must be appropriately protected. This has been carried out well in many localities in the past and the results have been fairly good. For example, in early March this year Wugang County Deputy Magistrate Yuan Fengshan went down to Zhuanwan District to conduct investigation and study. He also sent 13 technical cadres to carry out experiments in Lizuo production brigade in Zhuanwan commune. They conducted socialist education among the cadres and commune members in line with the guidelines of the "Summary of the Minutes of the National Rural Work Conference" and regained, for collective management, the four farms and orchards that had been equally divided among the households. They also seriously dealt with the commune members who had taken advantage of the opportunity to privately divide, forcibly take possession of or steal the collective fruit trees. By signing 3-year contracts with 63 laborers who had a strong labor force in their households and who had special skills for the management of the 12 farms and orchards in the whole brigade, they speedily changed the situation where nobody cared for the collective farms and orchards. We can draw on these experiences.

We should grasp the current favorable opportunity to grow well the industrial crop, such as fruit trees and tea, in the collective farms and develop diversified undertakings in order to consolidate and develop the collective economy.

BRIEFS

AQUATIC PRODUCTS CONFERENCE--The Hunan provincial conference on aquatic products held by the Provincial People's Government concluded in Changsha today. The conference looked into and discussed the principle, policy and measures of this province on speeding up fish production. Attending were responsible comrades of all administrative commissioner's offices and all autonomous prefectural, municipal and county people's governments who are in charge of aquatic products, and leading comrades of relevant departments and bureaus at the provincial level, some 200 people altogether. Governor Sun Guozhi attended and spoke. [Changsha Hunan Provincial Service in Mandarin 1100 GMT 12 Jun 82 HK]

PIG PROCUREMENT CONFERENCE--On 9 June the Hunan Provincial Commerce Department held a phone conference on the purchase and sale of pigs. The conference demanded that commerce departments at all levels do everything possible to develop pig production and arrange for ample market supplies. Departments must strengthen pig procurement and must not suspend pig procurement and lower grades and prices. They must do their best to satisfy the peasants' needs in selling pigs. They must arrange for ample supply of pork and increase the quantity of pork for cold storage. [HK141451 Changsha Hunan Provincial Service in Mandarin 2310 GMT 11 Jun 82 HK]

EARLY RICE FORUM--On 1 June, the Hunan Provincial Agricultural Committee held a forum of some leading comrades of the provincial agricultural department, the provincial agricultural institute and the provincial meteorological bureau and scientific and technological personnel to analyze the early rice growing situation and to look into the issue of tending early rice. The forum pointed out that due to the low technological level, many production teams have not grown early rice well. The forum held that it is necessary to tend early rice well and make good preparations against natural disasters. [Changsha Hunan Provincial Service in Mandarin 2310 GMT 3 Jun 82 HK]

RUNDOWN GIVEN FOR VARIOUS CROP CHARACTERISTICS

Nanjing XINHUA RIBAO in Chinese 17 Apr 82 p 2

[Article: "Summary of Wheat, Cotton and Oil-Bearing Crop Varieties Inspection and Approval as Meeting Specifications"]

[Text] On a previous occasion, briefing was provided on a first group of 10 paddy rice varieties examined and approved as meeting specifications by the Provincial Crop Varieties Examination and Approval Committee. Now, a brief account is provided on examination and approval of a first group of wheat, barley, and naked barley, cotton, sweet potatoes, soybeans, peanuts, rape, Chinese cabbage, and green manure.

Semi-winter wheat, "Ningmai No 6," was bred by the Provincial Academy of Agricultural Sciences. This variety tolerates fertilizer and resists lodging, shows strong tillering, has many spikes and numerous grains, is fairly resistant to cold, may be sown early, and has a fair potential for increased yields. However, ripening tends to be a bit late. It may be grown as an early or intermediate crop in places of intermediate or high fertility in the Huainan region.

Partial spring wheat, "Ningfeng," was bred by the Dafeng County Agricultural Institute. This variety ripens early and produces bumper yields, tolerates fertilizer and resists lodging, has large spikes and numerous grains, is fairly tolerant of cold, and is of fine quality. It is not resistant to wheat scab, however; its leaves wither during the late season, and ripening is poor. It may be planted in places of intermediate and high fertility along the Chang Jiang and in coastal areas.

Spring wheat variety, "Yangmai No 4" (i.e. 9 - 10 - 8 - 3) was bred by Yangzhou Prefecture Agricultural Institute. This variety has large spikes and heavy grains, is of good quality, and is only lightly affected by wheat scab. However, spikes tend to be few in number and tolerance of cold is fairly poor. It may be grown as an intermediate or late crop in Tongyang and Sunan prefectures in places where soil fertility is intermediate to high.

Intermediate maturing barley variety, "Yanfuaizaosan," was selectively bred by the Yancheng Prefecture Agricultural Institute. Plants of this variety are short and sturdy; it tolerates fertilizer and resists lodging, shows strong tillering, and has numerous spikes. However, it is prone to yellow leaf spot and netblotch. It also ripens poorly. It may be planted in Xuzhou, Huaiyin and Yancheng prefectures, and in areas of the province with only light disease infestation.

Intermediate ripening cotton variety "Xumian No 6" was bred by the Xuzhou Prefecture Agricultural Institute. Plant shapes of this variety are rather good; stems are sturdy; no early deterioration occurs; bolls are large; splitting of bolls occurs freely; color and luster of fibers is milky white; yields of both unginned and ginned cotton are higher than for "Xuzhou 142" and "Daizimian No 15," and physical properties are better than those of "Xuzhou 142." It may be grown in places where "Xuzhou 142" is grown.

Sweet potato variety "Huaishu No 3" (Huai 25) was bred by the Huaiyin Prefecture Agricultural Institute. This variety of sweet potato sprouts well, bears tubers early, has a drying rate as high as 35 percent, tolerates storage, tolerates dampness rather well, and is strongly resistant to alternaria leafspot. Carotene content is fairly high, and taste is good. But yields are just so so, and plants are prone to early deterioration during the late stage. It may be planted in the Huaibei area.

Soybean variety "Xudou No 3" was bred by the Xuzhou Prefecture Agricultural Institute. This variety is resistant to lodging, has a high fruiting rate, and ripens fairly early. It is poorly resistant to drought in the late stages, however. It may be rotationally cropped with wheat in the Huaibei region.

Peanut variety "Xuhua No 8" (i.e. 710 - 43) was bred by the Xuzhou Prefecture Agricultural Institute. This variety produces consistently high yields, is broadly adaptable, tolerates drought and resists waterlogging, flowers early, bears peanuts all at one time, and has numerous shells containing two peanuts. But it is not very resistant to lodging, and if protracted rainy weather is encountered during fruiting, rust infestations are serious and it is prone to early deterioration. It may be grown in sandy or black soil areas of moderate to high fertility where drainage conditions are good. It is not suitable for growing in baojiang soil [0545 3364 0964].

Rape variety "Ningyou No 7" was bred by the Economic Crop Institute of the Provincial Academy of Agricultural Sciences. This variety has good bumper yield qualities; its stems are hard; it develops well in spring, and oil content is high. Its shortcomings are little leaf age flexibility and poor resistance to cold, but it possesses strong ability to revive after freezing. It may be grown in the Huainan region.

Hybrid Chinese cabbage variety "Qingzazhongfeng" was introduced from Shandong by the Xuzhou Municipal Seed Station. This variety has high yields, broad adaptability, a high rate of usable cabbage, is fairly resistant to frost and mold, is tolerant of storage, and is rather good tasting. However, in drought years, it contracts virus diseases. It may be grown in places where fertility and water conditions are fairly good.

Green manure variety "Dajiajianshe wandou" peas was imported from France by the Provincial Botany Institute, the Soil Fertility Institute of the Academy of Agricultural Sciences, the Soil Fertility Department of the Farm and Forests Department, and the Xinyi County Green Manure Stock Varieties Farm. This variety branches strongly, has good root nodule development, plant nutrients are fairly high, seed toxicity is low, and it has fairly strong tolerance of cold, of dampness, of drought and of poor soil. It is also widely adaptable, but it ripens fairly late. It may be grown in the province.

Green manure "Xutiao No 8" Chinese trumpet creeper was bred by the Xuzhou Prefecture Agricultural Institute. This variety produces fairly high seed yields, ripens early, tolerates cold fairly well, tolerates late sowing, and is fairly adaptable. However, its resistance to leaf spot tends to be weak, and it does not branch strongly. It may be grown in the province.

JIANGXI

PEASANTS DEVELOP HILLY LAND

OW100905 Beijing XINHUA Domestic Service in Chinese 0747 GMT 9 Jun 82

[Excerpts] Nanchang, 9 Jun (XINHUA)--XINHUA editor's note: The experience of Fuzhou [2329 1558] Prefecture, Jiangxi Province, in helping commune members to manage well hills designated for personal use [zhi liu shan 5261 3966 1472] and hills of designated responsibility [ze ren shan 6307 0117 1472] merits our attention. At present, the "three fixeds" in forestry work--stabilizing hill and forest rights, delimiting the scope of hills designated for personal use and defining the forestry production responsibility system--is being carried out intensively in various parts of the country; many commune members are now taking care of hills designated for personal use and hills of designated responsibility. This is an important new idea that came along with the afforestation policy and an effective measure for mobilizing the initiative of the broad masses of peasants in developing forestry with greater, faster, better and more economical results. However, mass initiative cannot be boosted simply by defining hills designated for personal use and hills of designated responsibility; there is still a great deal of work to be done. The "Decision on Certain Questions Concerning Forest Protection and Forestry Development" issued by the CCP Central Committee and the State Council pointed out: "Hills designated for personal use (or barren sandy beaches) shall be assigned to commune members to have trees planted and grass grown on them for a long period of time." To mobilize the peasants' initiative, the masses must first be convinced of the importance of this provision; and second, they must be helped in solving the many problems concerning seedlings and saplings, capital and techniques. In short, a great deal of careful work still has to be done. (End of editor's note)

XINHUA correspondents Wu Zheng and Wu Zhicheng report: How do we make commune members afforest the hills designated for personal use of mountains of designated responsibility and cover them with greenery as quickly as possible after suitable forests and barren hills are assigned or contracted to them?

Last year Fuzhou launched a prefecturewide "three fixed" forestry work campaign to stabilize hill and forest rights, delimit the scope of hills designated for personal use and define the forestry production responsibility system. Of the more than 5.09 million mu of suitable forests and barren hills currently being held by collectives, over 1.17 million mu were assigned to commune members as hills designated for personal use and hills of designated responsibility. It was originally thought that the masses would start to plant trees as soon as the barren hills were assigned to the households. But, as it turned out, actual practice was not as expected. Mass initiative for planting trees was not very high after the hills designated for personal use and hills of designated responsibility had been contracted to the masses. The fact was that the masses did not dare to build timber forests because they were afraid that the policy might change as timber forests take longer time to grow. Furthermore, tree planting and afforestation require substantial technical knowhow and some commune members could not do the job for lack of scientific knowledge in this area. Some commune members did not have sufficient saplings, funds and manpower needed for afforestation and faced tremendous difficulties.

To solve all these problems, the various localities in Fuzhou Prefecture have done some effective work in the following areas:

1. Publicity was given to party policies and ideological education was carried out effectively.

2. The peasants were given rights to their advantage and the masses were allowed more material benefits. Many communes and brigades in Fuzhou Prefecture specifically provided that the forests built in the hills designated for personal use and the crops grown there belong to the individuals who cultivated them.

3. The state gave support and the collectives offered help. After the barren hills were assigned to the households, the state must continue to help and should not stop there by doing nothing further.

As a result of the above mentioned measures, the mass initiative for afforestation and for covering the areas with greenery in Fuzhou Prefecture was mobilized. Many commune members have grown Chinese fir, bamboo, fruits, tea, mulberry and oil-tea camellia in the hills designated for personal use and hills of designated responsibility. According to incomplete statistics, more than 98,000 mu of fir forests and over 78,000 mu of economic forests have been developed in the entire prefecture. Of this, bamboo acreage is six times, tea acreage four times, and tangerine and orange acreage three times as large as compared with last year.

BRIEFS

FRESHWATER FISH--The Jiangxi provincial people's government called a provincial freshwater fishery meeting in Nanchang from 30 May to 6 June. Vice Governors Wang Zhaorong and Zhang Guozhen spoke at the meeting. The meeting noted that Jiangxi's freshwater fish catch in 1981 was 1.71 million dan, 13.6 percent more than in 1980 and an all-time high figure. The meeting called for striving for a 15-percent annual increase in order to bring the total annual output to 5-6 million dan by the end of the 1980's, a target set by the central authorities. [Nanchan Jiangxi Provincial Service in Mandarin 1100 GMT 7 Jun 82 OW]

COUNTY HOG PROCUREMENT--By the end of May Jiangxi's Duchang County had fulfilled 66.2 percent of the hog procurement plan and overfulfilled the annual plan for hog deliveries to the state. The county now still has more than 219,800 hogs in stock. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 21 Jun 82 OW]

BRIEFS

COMBATS DROUGHT--Leading party and government comrades at all levels in Baicheng Prefecture, Jilin Province, have gone to the forefront of production to help commune members combat drought and protect seedlings. The prefecture has started up 11,000 motor-pumped wells to irrigate fields around the clock. Baicheng Prefecture has virtually not had any rainfall in over 50 days. About half of the prefecture's 9 million mu farmland are suffering from serious drought. Seedlings on 600,000 mu of cultivated fields have withered. All-out efforts are being made to salvage as many seedlings as possible. [SK210752 Changchun Jilin Provincial Service in Mandarin 2200 GMT 20 Jun 82]

WEATHER TREND--According to the Jilin Provincial Meteorological Observatory's forecast on 19 June, beginning in late June Jilin Province will experience more rainfall, and the temperatures will drop. The meteorological observatory urged all localities to make preparations for the forthcoming rainy season and take the opportune time to replant late fieldcrops. It also called for full preparations for torrential rains, floods and waterlogging that might occur in some localities because rainfall will be uneven in the flood season in 1982. [SK200830 Changchun Jilin Provincial Service in Mandarin 1100 GMT 19 Jun 82]

DROUGHT COMBATING--With the help of the state, the Jilin provinical people's government recently allocated 5.25 million yuan, 35,000 tons of chemical fertilizer, 1,030 tons of gasoline and 1,200 tons of diesel oil for combating drought and protecting seedlings in seriously-afflicted areas in the province. [SK170800 Changchun Jilin Provincial Service in Mandarin 1100 GMT 16 Jun 82]

JILIN DROUGHT EFFORT--Some 60 million mu of farmland, nearly half of Jilin Province's total, has been affected by drought since early June. Over 2 million people, 25,000 motor and animal driven carts and 20,000 motor-pumped wells are now working to combat drought. As of 18 June, the province had watered 2 million mu of fieldcrops. BRIEFS

RURAL LIVING STANDARDS--The Liaoning Provincial Statistical Bureau recently conducted a survey of 500 households in Gai, Fuxin, Jianping and 15 other counties. Results of the survey show that the peasants' living standards have improved markedly in the past 3 years. The 1981 per capita net income of the commune member was 306.6 yuan, an increase of 65.68 percent over 1978. In 1981 the number of rooms per household increased to 3.35 from 2.91 in 1978. [SK121208 Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 11 Jun 82]

PADDYFIELD IRRIGATION--In response to a request by Liaoning Province, the Jilin provincial CCP Committee and government released water from six reservoirs to help irrigate paddyfields in the lower reaches of the Liao He in Liaoning. The water flowed into Liaoning's Panshan County on 15 June. [SK181009 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 17 Jun 82]

CROPS DIE--Due to a serious drought, over 250,000 mu of crops in Jinxi County in Liaoning are withering and 20,000 mu of crops have died. The total amount of farmland in Jinxi County is about 830,000 mu. Each day the county dispatches over 100,000 people and utilizes 900 pumping wells to combat drought. Over 50,000 mu of crops are irrigated. [SK201059 Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 19 Jun 82]

BRIEFS

CASH CROPS--Harqin Banner sowed 160,000 mu of cash crops including oil-bearing crops, tobacco leaves, beets and medicinal herbs in 1982, accounting for 17 percent of the Banner's cultivated land. This banner has also developed household sideline occupations. The number of hogs in stock and the number of poultry 155,000 and 360,000 respectively. This banner now has 260,700 animals. The commune- and brigade-run enterprises of this banner has earned 3.52 million yuan, an increase of 5 percent over the corresponding 1982 period. [SK240642 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 Jun 82]

INSECT PEST--Zhuozi County and Siziwang Banner, in Nei Monggol Autonomous Region, have taken emergency steps to exterminate grass borers. Because of high temperatures, great numbers of grass borers have emerged in Xilin Gol and Ulanqab, posing a serious threat to pasturelands and farmlands. The two leagues are making vigorous efforts to exterminate the grass borers. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 11 Jun 82 SK]

BRIEFS

PREFECTURES DROUGHT--Hanzhong and Ankang prefectural CCP committees and administrative offices are taking emergency measures to lead the masses in fighting the drought and protecting crop seedlings so that a good harvest in autumn can be guaranteed. Since May, the drought in these two prefectures have become more and more serious. Summer transplanting and sowing have thus been seriously affected. Some early-autumn seedlings are faced with the danger of withering. Of the 1.5 million mu of rice fields which have been transplanted, about half have been seriously afflicted and 300,000 mu of them are full of cracks due to the drought. In a number of places, there is not enough drinking water for people and for animals. In view of the constant deterioration of the drought situation, emergency meetings have been held in the two prefectures and some counties, and have called for setting off an upsurge to fight the drought and "rush plant and protect seedlings." More than 500 cadres in Hanzhong Prefecture, led by the leading cadres, have been sent to the frontline of fighting the drought, and 400,000 yuan of the local finances in the prefecture and various counties has been mobilized to be used as subsidiary funds for oil and electricity consumed in the fight. Cadres at various levels in Ankang Prefecture have also gone to the communes and brigades to lead the fight. Up to 17 June, more than 220,000 people have been thrown into the fight against the drought in Hanzhong Prefecture and more than 190,000 mu of rice have been transplanted. COMMENTARY CALLS FOR COMBATTING DROUGHT

SK110950 Jinan Shandong Provincial Service in Mandarin 2300 GMT 10 Jun 82

[Station commentary: "Resolve to Combat Drought and Carry This Antidisaster Struggle Through to the End"]

[Excerpts] Our province has been plagued by serious drought for 3 successive years. It is unprecedented in history because it covered a large area, caused serious damage and lasted a long period. During the period between January and mid-May this year, our province only received 65 millimeters of rainfall, a decrease of 35 percent over the corresponding period of the previous normal years.

At present the drought situation is worsening. The continued high temperatures and dry and hot winds has resulted in a serious loss of soil moisture, posing a threat to the growth of wheat and spring seedlings. This serious drought has caused great difficulties to the province's industrial and agricultural production and the livelihood of the people. Encountering such serious drought, we have no choice but to resolve to combat drought, overcome difficulties and carry this antidisaster struggle through to the end.

At present our province's drought situation is worsening and it is a foregone conclusion that we will suffer a reduction in the output of summer grain crops. We must prepare for the worst situation and strive for the best. We must note that combatting drought and wresting a bumper harvest is not only a major economic task but also a major political task. It is the most important and urgent task among all our work. This is a matter concerning the current general situation. All party and government organs and all trades and professions must show concern for this general situation, serve it and arrange work around it. The party as a whole and all the people must unify thinking and make concerted efforts to combat drought.

The antidrought struggles in the past few years, especially the previous one, have fully shown that as long as we strengthen leadership, deeply mobilize and rely on the masses, and bring into full play all favorable factors we will overcome drought to a considerably great extent and will reduce losses. This spring, more than 90,000 cadres have gone to the countryside to work along with some 14 million laborers to combat drought. They have exerted great efforts in this regard. Thanks to the concerted efforts of the party, the government and army organs and civilians, our province has achieved noticeable success in the struggle to combat drought to ensure wheat growth and spring sowing. At present we have completed sowing of 46 million mu of spring seedlings in a timely manner in the province and the growing situation of these seedlings is very good. This struggle fully reflects the momentum of the party policies and the effectiveness of the responsibility system in agricultural production.

We must earnestly sum up the experiences gained in the previous stage of antidrought struggle, further strengthen our confidence and determination in overcoming drought, advance in the crest of victory and persist in carrying this antidrought and antidisaster struggle through to the end.

CSO: 4007/454

EARLY START REPORTED FOR COTTON PLANTING

Jinan DAZHONG RIBAO in Chinese 17 Apr 82 p 1

[Article: "Liaocheng Prefecture Farm Technicians Go Into the Frontlines of Spring Planting. Convey Scientific Cotton-Growing Techniques to Myriad Households, and to Farms and Fields"]

[Text] Liaocheng Prefecture has organized 1,200 farm technicians to go into the frontlines of spring planting to give guidance on the scientific growing of cotton in order to lay a foundation for winning a bumper cotton harvest this year.

As soon as cotton planting preparations began this year, all levels of the party organization in Liaocheng Prefecture transferred somewhat more than 1,100 scientific and technical personnel to the countryside to launch a campaign of "conveying techniques to households." Together with cadres sent to the countryside to inspect and direct spring plowing and production, they were able to go into cotton area communes and brigades to teach cotton growing techniques to cotton peasants. They explained everything step by step from how to level cotton fields, create soil moisture, and apply fertilizer to how to soak seeds to stimulate germination and use of furadantin and 39 for mixing with seeds; and from how to master the time for sowing to cotton planting density and spacing of rows and individual plants. More than 950,000 people heard their explanations. Scientific and technical personnel from Guan and Linqing counties also wrote technical articles titled, "Cotton Sowing From A to Z," "Farming Technique Model for Cotton Yields of 150 to 200 Jin Per mu," and "100 Questions and Answers About Cotton Production Techniques," which were printed and given to cotton peasants for study and reference. In Shen County more than 130 scientific and technical personnel went into the fields where, as a result of on-site inspection they discovered that the soil and the air had warmed up more quickly than in former years and that soil moisture conditions were good; 5 April was close to the right time for sowing. They suggested to the County CCP Committee the mobilization of the masses to get ready at once for planting. Beginning on 8 April, all communes and brigades throughout the county began sowing and planting one after another, just about 1 week ahead of the originally planned sowing time.

In order that the scientific and technical personnel might play a further role, the Liaocheng Prefecture CCP Committee and government administrative offices required county, commune and production brigade cadres to do the following: Prompt study of any reasonable suggestions made to scientific and technical personnel with positive adoption of all that fit local realities. Advanced cotton farming techniques put forward by scientific and technical personnel should be everywhere promoted through active organization of forces. Thus not only would confidence in scientific and personnel to do a good job of cotton planting techniques be strengthened, but the enthusiasm of the broad masses of cotton peasants for the scientific growing of cotton would be also aroused to assure smooth performance of spring sowing and production. Comparison of this year's spring sowing with that of former years shows six changes. One was destruction of the "arbitrarily uniform" regulation of many years standing that the cotton sowing season should always begin in mid-April. Acting on the basis of local soil and air temperatures, soil moisture conditions, and soil pH, each commune selected the right time for sowing. Second the cottonfield area in which soil moisture was created was increased 30 percent over last year. Third was scientific application of fertilizer, improvement being made in the sensible application of fertilizer. Average applications per mu of cottonfields were increased over last year by 0.5 cubic meters of organic fertilizer, 10 jin of phosphate fertilizer, 5 jin of standard chemical fertilizer, and 20 jin of seed cake fertilizer. Fourth was new development of farming techniques for saline-alkaline soil and for silted low-lying soil where seedlings grow and develop with difficulty. The entire prefecture practiced the growing of seedlings in pots containing nutriments and then transplanting them, and "ditching to avoid alkalinity planting methods" for an increase over last year of 1.5 and 2.3 fold respectively. Fifth was a more than one fold increase over last year in the area planted to "Lumian No 1" stock variety and to first and second generation seeds. Sixth was scientific soaking of seeds to force germination and improved use of furandantin and 39 chemical mixing of seeds. Right now the broad masses of cotton peasants are working hard at rush planting. As of 11 April, the daily sowing rate for the prefecture as a whole was more than 240,000 mu and it is anticipated that by the end of April the 4 million mu sowing task will have been completed.

BENEFITS OF GROWING CERTAIN FIBER PLANT DETAILED

Jinan DAZHONG RIBAO in Chinese 10 Apr 82 p 3

[Article by Provincial Science Commission Office: "Pay Attention to Development and Use of Bluish Dogbane"]

[Text] Bluish dogbane [apocynum venetum] also known as zeqima [3419 3344 7802] and chakezi [5420 2644 1311], is a member of the zhutao [4554 2711] family, and is a perennial, herbaceous, wild plant, plants growing between 1 and 4 meters tall, and roots going down to 2 to 3 meters. Because of its deep roots and profuse leaves, and its ability to withstand saline and alkaline soil and windblown sand, it can live for more than 20 years. It is found largely in places in China where the soil is saline-alkaline, where there are sandy wastelands, and where it is frigid. Coastal regions in the lower reaches of the Huang He also have tracts of wild-growing bluish dogbane. Near the military horse farm on Gu Island alone, there are several tens of thousands of mu of it.

Every part of bluish dogbane is valuable and has many uses as follows:

(1) Many medicinal materials can be derived from it. Bluish dogbane's leaves contain quercetin [2086 4122 4790], which can be used to make medicines that are remarkably effective in the treatment of high blood pressure, tracheitis, in making expectoration easy, in controlling asthma, in combating inflammation, and in combating allergies. It has been included in the 1977 national pharmacoepia.

The compound bluish dogbane tables produced by the Shanghai Pharmaceutical Plant are remarkably effective in the treatment of high blood pressure, and can get rid of headaches, dizziness, and tingling sensations in the limbs without side effects. The roots of bluish dogbane contain quercetin, strophanthin glycoside [3021 3029 2467 5363 1311 393A 0337], and acetylation derivative, four cardiac stimulant ingredients, which play a fine heart stimulant and diuretic role. They have a rather good curative effect on edema occasioned by nephritis, and they have few side effects. In addition, from the stems of bluish dogbane can be extracted cardiac glycosides and ingredients used in flavone type drugs.

(2) It can be used to make cigarettes, to make teas, and to make paper. The Chinese Herb Institute of the Chinese Academy of Medicine, the Northwest Plant Institute of the Chinese Academy of Sciences, and the Zhengzhou Tobacco Industry Institute of the Ministry of Light Industry have worked together with some

tobacco plants to trial develop a bluish dogbane herb cigarette containing 30 percent bluish dogbane leaves. It both maintains the flavor of real cigarettes and reduces the nicotine content. It also has a definite curative effect on the chronic tracheitis caused by smoking. Additionally, it can save on tobacco leaf and lower costs. Peasants in the bluish dogbane producing areas of China have long been in the habit of drinking bluish dogbane tea, and such use is also recorded in ancient books. Long time drinking of such tea lowers blood pressure, lowers blood fat, reduces phlegm, stops coughing, calms the nerves, and stimulates the heart. Beijing's Daxing Bluish Dogbane Tea Plant has an annual output of about 3 million jin. The rapidly dissolving bluish dogbane (which is dissolved in hot water) developed by the Beijing Municipal Food Industry Institute has been evaluated by medical units as a rather good drink for the prevention of illness and making the body healthy. It will soon be marketed. The bark fibers of bluish dogbane are a fine raw material for making paper. The pitch remaining after the bark has been removed can be used as a filler in making paper.

(3) It may be used as a high quality textile raw material. The bark fibers in the stems of bluish dogbane are finer than in [one character illegible] hemp, and the absolute strength of individual fibers is five to six times that of cotton, but the percentage elongation is small, being only about 3 percent. Fiber content is higher than for most hemp, and it is known in Shanghai textile circles as the "king of wild growing fibers." Units concerned in Shanghai have used bluish dogbane in combination with cotton, wool, and silk to trial manufacture more than 10 different kinds of textiles magnificent in color and both tough and soft at a 30 to 50 percent saving in cotton, wool, or silk raw materials.

Bluish dogbane is strongly resistant and is able to grow in strongly alkaline-saline and arid places with low temperatures and windblown sand. Planned transplantation and domestication would permit both development of infertile soil for use, rapid greening of areas, sheltering against wind and stabilization of sand, and improvement of soil and there would be no competition with grain and cotton for land. Full development of this resource for use can help development of commune and brigade enterprises and will enliven city and country markets.

A broad survey was made of bluish dogbane resources in the province during the early 1950's. However, since historical conditions at that time were limited, no development for use was done. With the passage of time, great changes have taken place in the status of resources in this regard in Hebei Province. Consequently, specialists concerned, professors, and researchers have made the following recommendations about bluish dogbane in Hebei Province: 1) First, an inventory of resources. They have recommended that the Provincial Agricultural Resources Survey Office make a bluish dogbane resources survey a part of plan, and after the inventory has been done that they be protected, growing increased, and resources developed. 2) Active promotion to application of existing scientific and technical results. They proposed that units concerned organize research personnel for the purpose of mastering the techniques of using bluish dogbane to make cigarettes and teas, and to extract drugs, place emphasis on experiments, trial manufacture, and production, and launch further research on multiple uses for bluish dogbane; 3) Organizing an attack on key problems.

Hebei Province is rather well endowed with scientific and educational forces on Chinese medicine and Chinese herbs, and many of the experts, teachers, and researchers who have been for many years engaged in research on multiple uses for bluish dogbane would like to come to Hebei Province to participate in this work. It is proposed that units concerned propose key problems that should be attacked and organize a cooperative effort to attack them.

EXPANSION OF AQUATIC PRODUCTS BREEDING REPORTED

Jinan DAZHONG RIBAO in Chinese 10 Apr 82 p 3

[Article: Actively Launch Aquatic Products Research Around Readjustment of the Fishing Industry. During Last 3 Years Shandong Province Has Had More Than 120 Individual Successes in Ocean and Fresh Water Breeding. Provincial Aquatic Products Science and Technology Work Conference Emphasizes Need To Do an Effective Job of Technical Promotion To Advance Great Development of the Fishing Industry"]

[Text] Shandong Province's aquatic products research units have won heartening achievements in actively launching research centering around readjustment of the fishing industry. Incomplete statistics show that during the past 3 years the province has scored research successes on more than 120 items, 46 of which have received citations by national units concerned and by the provincial government, and 4 of which have met advanced national standards.

In accordance with national aquatic products programs, both the Provincial CCP Committee and the provincial government have decided to undertake reorganization of the structure and distribution of the fishing industry, instituting "primary emphasis on nurture, a combination of nurture and catching, and economic diversification." In order to meet this need and bring about coordinated development of research, the economy and society, all aquatic products research units throughout the province have rapidly shifted the focus of their work to the breeding of numerous varieties of aquatic products, to rational use of resources and preservation of freshness in aquatic products, and to processing. They have devoted attention to technical problems in production urgently in need of solution and have carried out a coordinated attack on key problems. In ocean breeding, for example, artificial raising of shrimp is a job requiring little investment that brings large benefits and shows results quickly, but owing to limitations on the numbers of larva available in the past, this production has never developed. As a result of coordinated attack on the problem by research units concerned, within only a year's time success was achieved in the factorization of artificial breeding of larvae as a result of which the shrimp raising area was expanded. As a result of successful experiments in Yantai Prefecture using new techniques of breeding shellfish in the midst of algae that increases results in ocean breeding, the entire prefecture is now breeding mussels and scallops in separate kelp breeding areas, and they are growing nicely. Increased earnings for this year have been preliminarily estimated at about 2 million yuan. In order that shrimping in Bohai not injure large numbers of young fish after 2 years of efforts the Provincial Ocean Aquatic Products Institute has trial developed a new kind of net that permits the catching of shrimp with little damage to young fish. It is called the "shrimp drag No 1" net, and it has become one of the items promoted for use by the state.

Simultaneous with vigorous development of research has been attention to the introduction into China of foreign technology on the part of aquatic research units. The niluoluo [phonetic] African fish, which is native to Africa, grows quickly, produces high yields, and is strongly adaptable. It is a fine fish variety recommended tothe world by the United Nations Food and Agriculture Organization. After the Provincial Fresh Water Aquatic Products Institute introduced it into Shandong Province, following breeding experiments in breeding alone and breeding with other fish yields of 1,800 jin and 700 jin respectively resulted. Now wide area breeding is underway in some places.

The recently convened Provincial Aquatic Products Science and Technology Work Conference reiterated that simultaneous with the continued launching of research centered on reorganization of the fishing industry, all jurisdictions are to earnestly do an effective job of technical promotion work to bring about great development of fishing industry production.

The conference noted that Shandong Province has a long coastline, numerous beaches, and quite a few bodies of water within the province that provide very good conditions for breeding of aquatic products. However, a look at fishing industry production at the present time shows that not only is the breeding area still insufficiently large, but yields per unit of area also differ greatly from one place to another. In the realm of freshwater breeding of fish in ponds, for example, never mind achieving the more than 300 jin per mu yields of Guting Commune in Yutai County, even if the somewhat more than 170 jin per mu yields of Linyi County were to be achieved, annual total output of freshwater fish for the province as a whole would increase by more than 80 percent. Consequently, a great potential exists to be tapped. The key problem today is failure of technical promotion work to keep pace. All jurisdictions should act in the decisive spirit of the Provincial CCP Committee and provincial government in intensifying agricultural science and technology work for a genuine strengthening of leadership of aquatic products science and technology work, to build and perfect organizations for the promotion of aquatic products technology, and to give attention to the building of a technology promotion corps so that advanced aquatic products techniques can be extended to application and play a full role in fishing industry production.

In addition to transmitting the spirit of pertinent central government and provincial conferences, summarizing work and assigning future tasks, this conference also exchanged the experiences and plans of some prefectures and units. These included this year's assumption of responsibility by Linyi County for fish breeding experiments handed down by the Aquatic Products Bureau for "10,000 mu of continuous ponds for yields of 200 jin per mu," for which manpower and material preparations are currently actively underway.

SICHUAN TESTS MEASURES FOR RURAL TRANSFORMATION

OW111342 Beijing XINHUA in English 1239 GMT 11 Jun 82

[Text] Chengdu, 11 June (XINHUA)--Sichuan Province is pioneering in testing a major change in rural administrative and economic structures, which observers regard as vital to China's rural development.

Townships, which were abolished with the establishment of the people's communes in 1958, have been restored in Guanghan, Qionglai and Xindu Counties singled out by the provincial authorities for the experiment. The township government has replaced the people's commune as the basic government unit in the countryside. Villages as a layer of administration have also been restored to replace the production brigade which operated under the commune.

The economic affairs of the former people's commune are administered by economic organizations assuming different names, by "agriculture-industry-commerce" combines as in the case of Guanghan County. But in experiments carried out in other parts of the country, the people's commune remains to be an economic organization.

The township government is elected at the township people's congress while the village head and his assistant, or the "village clerk," are chosen through popular election. The township communist party committee now supervises over the implementation of the party's policies, rather than getting involved in the day-to-day work of the grass-root units as the former commune party committee did.

Provincial officials told XINHUA that the transformation is necessary because the commune set-up has the disadvantage of over-concentration of power, although it once promoted agricultural production.

The people's communes, which were set up in 1958, combined government administration with economic affairs. In other words, the commune is the basic government unit in the countryside and, at the same time, an economic organization.

The experiment being made in Sichuan Province aims at separating government administration from management of economic affairs, so that peasants and their collectives may have the initiative in their own hands in developing production.

Guanghan County, now with a population of 490,000 and 30,666 hectares of farmland, underwent a series of social transformation in agricultural collectivization in the 1950's, which culminated in the establishment of the people's communes in 1958. In 1957, when peasants were in advanced agricultural cooperatives, their annual income from the collectives averaged 68 yuan and 254 kilograms of food grain per capita. The corresponding figures for 1976 were 74 yuan and 267.5 kilograms, showing little improvement over the past.

Guanghan officials attributed this to the ultra-left policies that had been pursued before the overthrow of the gang of four. But over-concentration of power in the commune system was partially responsible, they said.

While transforming the commune set-up, authorities of the three counties have helped peasants institute the job responsibility system, under which payment is given according to output.

With initiative in their own hands, people in the three counties have set up economic entities including agriculture-industry-commerce combines by breaking the barriers caused by administrative divisions of villages, townships or even counties, rural collectives have in the past 3 years started 1,600 industrial and other enterprises yielding an annual output value of 220 million yuan, 4.6 times the figure for 1977, before the experiment began.

Good results have been produced through the experiment, provincial authorities said. From 1956 to 1977, the total value of industrial and agricultural output increased at annual rates of 4.5 percent, 2.2 percent and 3.4 percent for the Guanghan, Qionglai and Xindu counties respectively. The corresponding figures for the period between 1978 and 1981 were 14 percent, 20.6 percent and 16.5 percent.

PRECAUTIONS AGAINST FLOOD--The Xinjiang regional's people's government held its 12th executive meeting on 10 June, presided over by Chairman Ismail Amat, to discuss precautions against flood. The meeting demanded that the whole region vigorously step up antiflood precautions and rely on the masses to overcome flood disasters and reap a bumper harvest. The meeting pointed out: The region's weather has been abnormal this year. There have been cold waves, hailstorms and strong winds, and flooding has occurred in some places since late May. This has caused serious losses in industrial, agricultural and livestock production and serious difficulties for the people's livelihood. There may be further floods in north and south Xinjiang this summer, followed by drought in places. The whole region must therefore attach great importance to this problem and do a good job in antiflood precautions. Antiflood and relief work should currently occupy an important place on government agenda. The regional government has also issued an urgent circular on stepping up antiflood work. The circular made the following points: 1) Enhance understanding of the harm done by floods; 2) get a good grasp of current disaster relief work, make proper arrangements for the masses' daily life, and also conduct education in the spirit of self-reliance; 3) inspect the state of antiflood precautions; 4) leaders at all levels must get a good grasp of this work, go to the frontline and teach the masses to display the spirit of self-reliance. "They must also step up ideological and political work and expose various rumors misleading the masses. It is necessary to strengthen security work and deal resolute blows at criminals and counterrevolutionaries who sabotage the work of fighting and relieving disaster." While acting against floods, it is also necessary to take precautions against drought. [Summary] [HK130551 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 12 Jun 82]

ANIMAL HUSBANDRY CIRCULAR--The Xinjiang animal husbandry department recently issued a circular demanding that all places do well in livestock production during the summer. It is estimated that the number of young livestock in the region this year will be more than 10 million head for the first time. However, since summer last year, the region has had dry weather. In particular, there was little rainfall this spring. The drought situation in the pastures is serious and grass has not grown well. This has made this year's livestock production in the region, all places must continue to strengthen leadership over livestock production, perfect the livestock production responsibility system, do well in preliminary distribution work, make full use of all water sources to irrigate pastures and to increase grass production and do well in preventing and treating livestock diseases. PREFECTURE ACTS SWIFTLY TO BOLSTER TEA PRODUCTION

HK150417 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 14 Jun 82

[Summary] "Having found out problems emerging in spring tea production, the Lincang Prefecture CCP Committee strengthened investigations in grassroots units, took appropriate measures in good time and thus promptly checked spring tea production from dropping."

In the beginning of the spring tea harvest season this year, two deputy secretaries of the Lincang Prefecture CCP Committee who were carrying out investigations found that the production responsibility system had not been well implemented in some communes, production brigades and primary tea processing plants; and that tea products, out of the control of the procurement plan, were flowing out from some places. This situation had made the tea production of the prefecture lower than the production in the same period last year. To cope with this declining trend, the prefectural CCP Committee carried out further investigation. A circular was issued later, urging counties and communes to strengthen leadership, improve the production responsibility system and solve problems in production and procurement. On the other hand, the prefectural CCP Committee also took appropriate measures to improve the procurement work, establishing tea inspection centers and strengthening market administration.

"With the adoption of the above measures, the production of spring tea in the prefecture has been rapidly improved. By 20 May, the prefecture had procured more than 3,100 dan in excess of the same period last year."

PIG FEED MEETING--To speed up the popularization of compound pig feed and ensure the fulfillment of the quota for raising 1 million pigs this year in Yunnan Province, the Yunnan provincial animal husbandry bureau recently held a meeting in Kunming. This meeting was attended by the directors of the animal husbandry and agriculture bureaus of all prefectures, autonomous prefectures and municipalities and some counties. The meeting seriously examined the progress of the popularization of compound pig feed in all places, exchanged experiences, looked into some problems which should urgently be solved in the course of work and arranged for work in the second half of this year. From January to April, 92 counties throughout the province conducted experiments in and demonstration and popularization of compound pig feed, produced and supplied some 11.2 million jin of compound pig feed and fed some 113,000 pigs, some 70,000 pigs more than in the corresponding period last year. They also fed some 160,000 chickens with compound feed. The meeting urged the province to speed up the popularization of compound pig feed. [Kunming Yunnan Provincial Service in Mandarin 1100 GMT 12 Jun 82 HK]

RAINY SEASON STARTS--Since the beginning of June, it has rained throughout Yunnan Province. The rainy season has started in the major part of the province. According to statistics compiled by the provincial meteorological observatory on 11 June, except for an average rainfall of less than 30 mm in 13 counties, including Qiaojia, Jinning, Yiliang, Chengjiang, Jiangchuan, Tonghai, Yuanjiang, Lufeng, Shuangbai, Chuxiong, Mouding, Yongsheng and Binchuan, the average rainfall of the other places in the province was between 30 mm and 155 mm. The major part of the province has alleviated the drought situation. [HK161344 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 12 Jun 82]

RESERVOIR MAINTENANCE--From 1979 to the present, Yunnan Province has reinforced and repaired some 280 small-size No 1-type reservoirs and above, which accounts for over 79 percent of the reservoirs which should be reinforced and repaired. Prefectures and autonomous prefectures, including Yuxi, Chuxiong, Baoshan and Zhaotong, have basically completed the work of reinforcing and repairing their small-size No 1-type reservoirs. The province now has some 4,000 small-size No 1-type reservoirs, the majority of which were built in the late 1950's. At that time, stress was laid on high speed and large capacity, and the flood-control standards were low and their quality was poor. In the flood season every year, collapse accidents often occur. Since 1979, the province has gradually stepped up the management of the reservoirs. In each flood season from 1978 to 1981, the province appropriated special funds of some 50 million yuan to strengthen the maintenance of the reservoirs. TITLE: "Agricultural Field Subterranean Pipe Drainage Technology"

SOURCE: Beijing SHULI SHUIDIAN JISHU [WATER CONSERVATION AND HYDROELECTRIC POWER TECHNOLOGY] in Chinese No 5, 20 May 82 pp 42-49

ABSTRACT: Subterranean pipe drainage measures have been adopted in South and North China in recent years in the course of basic construction of fields and in Feb 79 and Aug 81 2 national conferences were called to discuss the special subject of underground drainage and irrigation. In China, experiments with subterranean drainage techniques actually started in the late 50's in Henan, Jiangsu, etc, and by the late 70's they were preliminarily extended to the lowland areas of Jiangsu and the lake plains of Zhejiang. It is estimated that about 5 million mu in the country have underground drainage devices which include subterranean pipes, hidden channels, etc. and of these, about 600 thousand mu have subterranean pipes. The use of subterranean pipes for drainage in the USA, the USSR, England, Czechoslovakia, Poland, Egypt, Japan, W. Germany, etc. is briefly introduced. The selection of proper caliber and construction material for the pipes, the drainage area for various sizes of pipes, the choice of filtering and insulating materials for the pipes, the depth and spacing of pipe installation, the horizontal and vertical arrangements of pipes, the management of subterranean drainage pipes, and the method of assessing the economic benefits and the investment return of a pipe drainage system are introduced in some detail. The "Drainage Manual" published by U.S. Bureau of Reclamation is cited to show the method of computing the load of pipes of different materials and structures.

TITLE: "Studies on the N-banding Karyotype of Cultivated and Wild Barley"

SOURCE: Beijing YICHUAN XUEBAO [ACTA GENETICA SINICA] in Chinese No 2, 1982 pp 160-164

TEXT OF ENGLISH ABSTRACT: It was found that all seven pairs of chromosomes of cultivated and wild barley possess centromeric banding, that a few of the chromosomes have near centromeric banding, and that most of the chromosomes also have interstitial bands. But the number and position of the interstitial banding in the long or short arms of these chromosomes show some variation among the cultivated and wild barley. It was observed that the banding pattern of the "bottle-shaped" wild barley was similar to that of the six-rowed wild barley, and the banding pattern of the six-rowed wild barley was also near that of the cultivated barley. Therefore, cytological research revealed that cultivated barley is closely related to wild barley.

TITLE: "Preliminary Study on the Starch-filling Principle of Wheat"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 4, 1982 pp 6-11

ABSTRACT: The stage after heading and before harvest is very important regarding the weight of wheat grain which may vary a great deal depending upon the weather and the cultivation conditions. For the local breeds in the prefecture, the grain test weight (weight of 1000 grains) may vary from 30 g to 44 g. For the purpose of clarifying the grain formation, starch filling, and ripening processes of wheat, 30 plants of 6 breeds which developed heads and blooms on the same days were marked for observation to record the variation of the length, width, thickness, and volume of the grains, the variation of green weight, dry weight, and moisture content of the grains, the condition of accumulation of dry substance in the grain, and the speed of starch filling of the various breeds. It was observed that from blooming to ripe, about 34-38 days are required and these days may be divided into 3 stages: (1) Grain formation stage takes about 10-13 days following blooming and about 20 percent of the total dry weight is accumulated in this stage; (2) Starch filling stage takes 17-20 days, during which the average increase is about 1.7 g/day; (3) Grain ripening stage takes about 4-8 days and the weight gain is about 6 percent of total. These facts indicate that the period of 10-32 days after blooming, i.e. the starch filling stage is the most important for dry substance accumulation and measures of disease and pest control, drought and flood protection, etc. adopted during this stage can increase the weight of the grain effectively.

TITLE: "Some Characteristics of Temperature Variation in China in the Present Century"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 2, 1982 pp 198-208

TEXT OF ENGLISH ABSTRACT: The monthly mean temperature at 137 stations in China in the present century was classified into five grades, i.e. grades 1-5. Maps of grade distribution have been prepared for every month and year. According to the intensity of cold or warm areas, the monthly temperature grade distribution is classified into five types: cold (C), warm (W), sub-cold (Cw), sub-warm (Wc) and normal (N). For every month, mean grades are computed for seven regions: northeast China; north China, middle and lower Changjiang; south China; southwest China; northwest China; Xinjiang.

Based on the above materials statistical analysis of the occurrences and secular variation of the five types are made and associations among the regions are studied. The characteristics of temperature variation of the past 30 years are discussed.

[Continuation of QIXIANG XUEBAO No 2, 1982 pp 198-208]

These results are useful for understanding the climatic change in China and may serve as background for long-range forecasting.

TITLE: "Potential Evapotranspiration in Ningxia District"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 2, 1982 pp 219-228

TEXT OF ENGLISH ABSTRACT: Using Penman's formula, we computed the natural evaporation E_r of Ningxia districts, and studied its distribution. The ratio E_r/r (aridity index) is used as the index for agroclimatological division. The formula $E_r = K_t E_0$ is used to compute E_0 for spring, summer and autumn. The proportion coefficient ($j_t = f_c/E_0$) between E_0 and field evaporation f_c is used as a moisture index for major growth periods of wheat, paddy rice and millet. Based on this information, irrigation requirements are studied.

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 1-8

TEXT OF ENGLISH ABSTRACT: Shoot formation was successfully differentiated from calli of the stem, leaf and hypocotyl of ramie (Boehmeria nivea L.) in the MS + 6 - BA 2-3 mg/l medium, and the axillary buds developed from these shoots could grow normally. When these shoots were transplanted to ½MS + NAA 0.2 mg/l medium, they regenerated into complete plantlets which could grow up normally in the field. We used the method of axillary buds for rapid propagation, and it could produce a greater number of tube plantlets free from morphological variation within a short

[Continuation of ZHONGGUO NONGYE KEXUE No 2, 1982 pp 1-8]

period. It could satisfactorily meet the need for the propagation of fine ramie varieties and the acceleration of breeding programs. In addition, the influence of different plant hormones on root growth was studied. In the ½MS + IAA 0.1 ppm + NAA 0.2 ppm medium, the roots could grow more prosperously and strongly. A whole series of transplanting techniques have been obtained.

TITLE: "Cytological Observation of Pollen Development in the Main Male Sterile Types of Rice (Oryza sativa L.) Developed in China"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 9-14

TEXT OF ENGLISH ABSTRACT: The male sterile lines of rice developed in China can be divided into three types (i.e., Wild-aborted type, Honglian type and Yunnan No 1) according to the cytoplasm source of the male sterile lines and the relation between the fertility restoring lines and the maintainer lines.

Cytological observation revealed that the abortion of microspores in different types of male sterile lines occurred at different stages. The abortion of microspores of the Wild-aborted type took place at the uninucleate microspore stage, that of the Honglian type at the two-celled pollen stage and that of Yunnan No 1 type at the stage just before the mitosis of reproductive nucleus.

In this paper the cytological process of pollen abortion was described and the relation between the manifestation of male sterility and the nucleus-cytoplasm interaction in rice was discussed.

TITLE: "Breeding by Anther Culture in Rice Varieties Improvement"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 15-19

TEXT OF ENGLISH ABSTRACT: Anther culture in rice improvement has made certain progress in China. A great number of anther-cultured rice varieties with various superior characteristics have been developed and started to be popularized in production. On the other hand, experiences have been systematically accumulated on the technique and working procedure of anther-culture breeding.

Most achievements gained from breeding by anther-culture are now used for stabilizing the segregation of characteristics in the early generation of intervarietal cross or hybrid rice, and are being used in remote hybridization and artificially induced mutation.

[Continuation of ZHONGGUO NONGYE KEXUE No 2, 1982 pp 15-19]

The anther culture method has not only bred new varieties of rice, but also synthesized a new, specific genotype that had never been found in local or exotic germ plasm and, hence, can perform an important function in the establishment of a new germ plasm bank.

TITLE: "A Preliminary Study of the Green-vernalization in Wheat"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 20-23

TEXT OF ENGLISH ABSTRACT: Experimental work on the green-vernalization in wheat for the acceleration of generation advance of both weak-winter and winter varieties was done five times in 1975 and 1980. Some wheat varieties with different growing habits in winter or spring were selected as tested materials. The results showed that: 1. The normal heading date of winter varieties can be accelerated and the vegetative stage shortened by treatment with green-vernalization; 2. The optimum days for treatment varied with the type of winter or spring varieties; 3. The effect of green-vernalization is much better than that of seed-vernalization.

TITLE: "Advances in the Studies of Wheat Cultivation in China"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 49-54

TEXT OF ENGLISH ABSTRACT: A lot of studies have been done on the rules for high yield and wheat cultural practices in getting massive bumper crops since the founding of the PRC. Results of these studies played an important role in guiding the wheat production and developing the cultural science. This paper covers the following aspects: (1) study on the stands structure in the fields; (2) study on the developing population structure; (3) study on the factors of yield components; (4) study on the rules of fertilizer and water requirements; (5) study on the index of control-promotion management; (6) study on the ways to obtain high yield; (7) study on the systems of cultural practices. The paper emphatically elaborates the main contents and present advances in the above studies with necessary evaluations. Ideas about future prospects, major subjects and methods in wheat cultivation studies are given in the conclusion.

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 2, 1982 pp 55-62

TEXT OF ENGLISH ABSTRACT: With an aim to search for botanical insecticides of good environmental quality for the control of rice insect pests, experiments have been carried out on 40 species of botanical insecticides against the rice yellow stem borer (*Scirpophaga incerulas*) in South China. Ethyl alcohol extracts of the seed kernels of two species of chinaberry (*Melia azedarach* and *M. toosendan*), acetone extracts of the leaves of *Rhododendron molle* and the root bark of *Tripterygium wilfordii* had very marked systemic action on the newly-hatched larvae and also some antifeedant effects. Extracts from the root bark of the bitter-tree (*Celastrus angulata*) had marked systemic properties, too.

The unique insecticidal properties of some species of Chinese plants, particularly Meliaceae, which are safe both to the environment and to the natural enemies of

[Continuation of ZHONGGUO NONGYE KEXUE No 2, 1982 pp 55-62]

insect pests, and their compatability with the agroecosystem emphasizes their potential value in the integrated control of rice insect pests.

TITLE: "Continue to Proceed With the Propaganda Eudcation of 'Two Unchanged' and 'Three Considerations'

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 5 May 82 pp 2-3

ABSTRACT: The "Outline of the National Rural Village Work Conference" is an extremely important document, in which the propaganda education of 2-unchanged and 3-considerations forms one of the essential contents. The propaganda education is to make the farmers understand that China's agriculture must stay on the socialist collectivism road; i.e. from the long term viewpoint, the public ownership and the production responsibility systems will be unchanged, and all three aspects of the nation, the collective, and the individual have to be taken into consideration and consideration of one at the expense of the other two is unacceptable. As it is clearly stated in that document, in the period between the winter of 1981 and the spring of 1982, centering on the job of establishing and perfecting the production responsibility system, all areas and regions should carry out this education in combination with problems of thoughts and practices. Since the conclusion of the conference, not a few cadres of the basic level have been unwilling, unable, and afraid of carrying out this job of propaganda eduction. The paper blames their own inadequate education for this problem; i.e. their leftist errors are insufficiently cleansed. The paper purports to help resolve this problem.

ORG: Survey and Investigation Group, Legislative Committee, National People's Congress Standing Committee

TITLE: "Survey Report Concerning the Problem of Unity of People's Commune and the Political Organization"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 5 May 82 pp 6-9

ABSTRACT: The Survey and Investigation Group has organized many symposiums to study the problem of the people's commune system and to gather the opinions of the leaders of communes and brigades, the county, prefecture, and provincial committees, and some economists. The group has learned from these symposiums that most comrades of the provincial, municipal, prefecture, and county committee hold the opinion that the political and commune organizations should be separate while most of the comrades of the communes hold the opinion that the existing condition should be maintained. Essential problems in separating the two organizations are discussed. To separate the two is mainly to promote yield increase, to develop productivity, to establish socialist democracy, and to strengthen the exercise ofc leadership of the party. The separation will create a unified political power organization as well as a flexible and various economic organization. The administrative and the economic regionalization [divisions in geography] may either be the same or be different. The idea of separating the two appears to be supported by the Survey Group yet the paper also appears to refrain from positive endorsement beyond examining the advantages and ways and steps of carrying it out.

I. GENERAL INFORMATION

FLOOD PREVENTION MEASURES EXAMINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 16 May 82 p 1

[Article: "Overcome Paralyzed Thinking and Take Flood Prevention Work Firmly in Hand. Water Conservancy and Electric Power Ministry Deputy Minister Li Boning [2621 0130 1380] Makes Statement to Reporters"]

[Text] Water Conservancy and Electric Power Ministry Deputy Minister Li Goning issued a statement to the newspaper's reporters about this year's flood prevention work.

Comrade Li Boning spoke first about mental mobilization work. He said that during the 1981 flood season the upper reaches of the Chang Jiang, the upper reaches of the Huang He, southern Shaanxi, southern Liaoning, Heilongjiang and the southeastern seacoast were beset with floods, and that under the leadership of the CCP Central Committee and the State Council great achievements were won in the struggle against floods. Numerous water conservancy and hydroelectric power projects played a very great role in flood prevention. Now South China has entered the flood season, and soon the flood season for North China will arrive. Of extreme concern to all is that in the lower reaches of the Huang He, the middle and lower reaches of the Chang Jiang, in the Huai He, the Hai He, the Songhua Jiang, the Liao He, and the Zhu Jiang for more than 10 to 20 years to large floods have occurred. This situation deserves a high degree of vigilance.

Inasmuch as the wide plains areas of China have not experienced large floods for many years, and particularly since the North China region has had little rain and drought conditions for 4 to 5 consecutive years, some cadres and masses have developed paralyzed thinking about waterlogging and flooding. Some even feel that so long as there is no drought, even if a flood as big as the 1963 one occurs, there is no need to be afraid. In places where large floods occurred last year, some people supposed that floods will not occur again this year. Historical records show that in many areas drought occurred first followed by waterlogging, or that there were consecutive years of flooding. Consequently such a mentality of fearing only drought but not fearing floods, and a mentality of trusting to luck that no large floods will occur this year are extremely lopsided and harmful. All levels of flood prevention, water conservancy and electric power units must wideranginly arouse the masses and do effective mental mobilization work under the leadership of local CCP committees and government, both to give attention to current work to fight drought and also to do a solid job of preparing to prevent floods. Only by being ever prepared can one be in an invincible position.

Comrade Li Boning continue by speaking about the several tasks currently requiring urgent attention.

1. Urgent Attention to inspection of Flood Prevention. Water conservancy projects such as water courses, dykes, culvert floodgates, and reservoirs, no matter whether flood inspected last year or no matter that there have been no floods and they have not been flood inspected for many years, must be inspected prior to the flood season for project safety, for project quality, and for ability to prevent floods. When deficiencies and problems are uncovered in the course of inspection, resolute action must be taken and conscientious handling done. When there are problems that genuinely cannot be readily handled before the flood season, provisional measures for quick protection and safety must be formulated in an effort to reduce damage in the event of a large flood. Emergency materials should be made ready before the flood season.

2. Firm Attention to the Removal of Obstacles That Block Water to Assure the Rivers Ability to Carry Flood Waters Away. In recent years some units have built structures that block the water, and have grown plants that block the water within watercourses or along their edges. They have built houses and industrial plants and have dumped ashes and refuse that block watercourses and impede movement of flood waters. Flood waters can be abruptly stopped and dikes breached to cause disaster. These lessons must be conscientiously absorbed. To this end, all levels of flood prevention units must consciently dispose of obstacles in the way of flood waters in water courses under the centralized leadership of CCP committees and government. They should adhere to a policy of "whoever has erected the obstacle shall remove the obstacle," and this work is to be completed before the flood season.

3. Preparatory Work on Arrangements for the Masses in Floodwater Storage, Flood Detention and Floodwater Movement Areas. In a spirit of a high degree of responsibility for the people, preparations for mass warning systems, dispersal, and movement of people living in floodwater storage, flood detention, and floodwater movement areas must be done to prevent loss of people's lives and property.

4. All Levels of Hydrology and Meteorology Units to Continue to Diligently Work at Metererological and Hydrological Monitoring and Forecasting. All levels of flood prevention units and posts and telegraphs units should strengthen cooperation to do a good job in assuring communications, the upward transmission of information from below, the transmission of orders promptly and accurately, acting as staff officers for all levels of flood prevention command units.

5. Need for Coordinated Warfare in the Struggle Against Floodwaters. All flood prevention work involving neighboring areas of fraternal units anywhere should be done with unity and cooperation, with safety first, with concern

for the overall situation, and with obedience to the unified control of superior authority to achieve the goal of common protection and mutual benefit. Those who refuse to cooperate, shift troubles to others, show no concern for the overall situation and will not submit to control must be investigated and responsibility fixed or have responsibility fixed according to law.

USE OF TRADITIONAL ORGANIC FERTILIZER ENCOURAGED

Beijing RENMIN RIBAO in Chinese 6 May 82 p 1

[Short commentary: "Develop the Tradition of Organic Farming"]

[Text] In agriculture, each locality in our country has accumulated some experiences in production suitable to itself after a long practice. We should highly regard these traditional experiences, assimilate their essence, and energetically popularize them in order to serve agriculture today.

Some people believe that since we are now striving for agricultural modernization, the old production techniques are no longer suitable and should be discarded to make room for modern techniques. This is a one-sided view. It must be admitted that some traditional agrotechniques and farming methods are backward and no longer useful. However, we must also be aware that there are others which are still very useful and which should be inherited and developed. For example, in either the north or the south, in the mountainous areas as well as the plains, and in dry land as well as paddy fields, the time-honored method of making organic fertilizers through energy recycling in agriculture, and the method of organic relationships in agriculture and so forth should be not only highly regarded now but also of great value in the fairly distant future. The immediate benefits of organic farming, which consumes less energy because of the recycling, are lower production costs and higher efficiency. In the long run, it will keep the land constantly fresh and reduce pollution, thus contributing to human welfare. This matter is now continuing to attract attention even among those countries where agrotechnology is fairly advanced.

Unfortunately, some localities do not attach much importance to the use and development of traditional agrotechniques. Because of the gradual increase in the output of chemical fertilizers, they have slackened their efforts in accumulating organic fertilizer. Also, some localities have cast aside their production techniques, which have proved to be effective, while paying their undivided attention to learning from advanced foreign techniques. Practice has proved these practices to be harmful. These localities should learn from the methods used in the Suzhou areas.

Traditional agrotechniques are closely related to the spirit of hard struggle. If we want to restore the fine traditions in agriculture, we should display the spirit of hard struggle. We must follow the example of the laboring people before us in our country, in order to win bumper agricultural harvests through hard work and sweating. As long as we highly regard our fine traditions and at the same time assimilate the advanced techniques at home and abroad, our agricultural production will certainly make quicker progress.

BRIEFS

TYPHOON REDUCED TO LOW PRESSURE SYSTEM--The Central Meteorological Observatory this afternoon released the following information: This year's typhoon No 5 was reduced to a low pressure system this afternoon. The center of the low pressure system was located over waters off eastern Guangdong, and winds near the center still ranged from wind force 6 to 7. The low pressure system is slowly moving northeasterly. As a result of the low pressure system, winds will range from wind force 6 to 7 in the northern area of the South China Sea and Guangdong's coastal areas from tonight to tomorrow. There will be heavy to torrential rains in eastern Guangdong and southern Fujian. [Text] [OW301435 Beijing Domestic Service in Mandarin 1200 GMT 30 Jun 82]

CONFERENCE NOTES POOR STATE OF FLOOD PREVENTION

Fuzhou FUJIAN RIBAO in Chinese 10 May 82 p 1

[Article: "Much Rain During This Year's Flood Season. Need For Early Precautions Against Floods. Provincial Flood Prevention Conference Proposes Action to Overcome Paralyzed Mentality For Implementation of Flood Prevention, and Strict Attention to Project Safety Inspections Before Flood Season for Early Elimination of Hidden Dangers"]

[Text] According to meteorology department forecasts, rain volume will be fairly great during this year's rainy season and there will be appreciable flooding in the Min Jiang basin. How can a good job of flood prevention be done this year? The provincial flood prevention work conference which concluded not long ago, proposed a program to overcome paralyzed mentality for diligent action primarily in prevention, the emphasis on prevention rather than a crash program, and for intensification of water conservancy project management to assure project safety so that reservoir projects will have no dam collapses and so that no breaks will occur in major dikes.

This year when the nine planets line up is an extraordinary year for astronomy, and calamitous weather may occur. During the past several years quite a few places in Fujian Province have not experienced much flooding, and numerous projects have not had to withstand the test of floods; this, the problem of hidden dangers in quality have not been eradicated. For small (2) reservoirs with a capacity of 100,000 to 1 million cubic meters, in particular, the dangers are rather serious. Reports from Jinjiang Prefecture say that 59 of the 335 reservoirs of this type in the prefecture have low flood prevention standards; quality is poor; and problems with hidden flaws have not been taken care of. A similar situation exists elsewhere. More than half of the province's more than 1,800 reservoirs have no designated persons in charge. Standards for flood prevention dikes and for sea walls to prevent floods and brake the tides are even lower. Numerous flood prevention dikes have been built on a sandy foundation, and leaks in the foundations of the dikes and in the dikes themselves is serious. Some units and individuals erroneously suppose that they can rest easy without concern because year after year flood prevention is called for but floodwaters never appear. They enclose river shallows to make farmland, build plants and construct houses, and build roads on dikes at will, thereby seriously reducing abilities to drain away flood waters. In addition, silting raises the height of river beds, and flood prevention standards become ever lower. In some places they dig away at the dike footings at will, remove stones from the dikes, and destroy dike works. Most small flood dike projects under control of communes and production brigades have had no one responsible for management for a long time. When small holes appear, no one repairs them. Delegates to the conference acknowledged that with the arrival of the flood season now, all jurisdictions should direct full attention to the aforestated problems, should genuinely strengthen leadership, should institute measures to guard against floods, and take preventive measures against possible trouble.

The conference emphasized the importance of reservoir and dike work safety as the focal point of anti-flood work, and the need to establish responsibility systems. In Shaowu and Songqi counties, the county people's government's assignment of responsibility for each and every reservoir and for dike sections to principal leadership cadres in the county, communes, and brigades is a workable method. A technical appraisal of every reservoir project should be made, and where problems with hidden flaws in quality exist, water storage should be limited. Storage of water should not be allowed in dangerous reservoirs. Where structures have been built in watercourses that impede the flow of water, anti-flood command units are responsible for clearing the obstacles. They should conscientiously study the problem and formulate plans in accordance with the principle of "whoever put up the obstacle is responsible for taking it down" to remove obstacles over a period of time to assure that flood water safely pass through reservoirs and major dike projects.

The conference noted that management of existing water conservancy projects must be improved, the focus of water conservancy work being solidly shifted to management. Reorganization of water conservancy management units should be done one by one over a period of time in the same way that enterprises were reorganized. Leadership teams should be augmented, labor discipline should be strengthened, responsibility systems should be established, regulatory systems should be improved, and a good job of economic accounting should be done.

BUMPER WINTER WHEAT AND BARLEY HARVESTS REPORTED

Fuzhou FUJIAN RIBAO in Chinese 15 May 82 p 1

[Article: "Much Planting of Wheat and Barley Last Winter for Bumper Harvest This Spring. Wheat and Barley Total Output and Per Unit Yields Reach All-time Highs in Longhai, Fuqing, Shanyou, and Dongshan"]

[Text] Last year Longhai, Fuqing, Shanyou, and Dongshan counties made winter planting a major crop. They strengthened leadership, obtaining bumper harvests of barley and wheat this spring. In these four counties, both total output and yields per unit of area of wheat reached all-time highs. In Fuqing County, output totaled more than 10 million jin more than last year, an increase of 27 percent. Donghsan County's yields per unit of area increased by 106 jin over last year for a 57 percent increase.

These four counties have been in the habit of doing winter planting, but last year when they put into effect their barley and wheat planting plans many commune members had only a feeble conception of the country and there were problems about fulfillment of barley and wheat growing plans. Leaders in all of the counties focused on this situation, leading cadres into communes and brigades to conduct socialist indoctrination of the peasants to induce them to plant according to state plan. Longhai County adopted measures whereby leaders assigned sole responsibility for individual tracts, and county leadership comrades led cadres and farm technicians into communes and brigades to carry out ideological and political work. They repeatedly publicized the favorable conditions for the growing of winter barley and wheat, and very quickly implemented plans for the growing of 133,000 mu. In view of the existence in Fuqing County of a mentality of "growing wheat and barley is not worthwhile," leaders educated commune members in the advanced experiences of Yutang Brigade in the county, which last winter fertilized with more barnyard manure than usual producing yields of more than 420 jin per mu of wheat and 1,000 jin per mu of early paddy. This increased everybody's confidence about engaging in production of barley and wheat. Barley and wheat growing in the county increased from 170,000 mu to more 906,000 mu, exceeding plan by more than 6,800 mu. Dongshan County instituted its barley and wheat growing plans in every peasant household, and also organized the signing of planting agreements between individual peasant households and production teams, thereby smoothly fulfilling planting quotas handed down by higher authority.

Scientific growing of wheat and barley to increase yields per unit of area was yet another major reason for these four counties bumper barley and wheat harvests this year. Longhai County and Shanyou County promoted the wide area growing of "Furong 16 (or 17)," and Fuqing County's seed company bought and allocated Jin line superior wheat varieties for the sowing of 63 percent of its area. In addition, the county planted Zaoshu No 3 barley, the area of the county planted to fine varieties totaling 85 percent. Longhai and Donghsan counties changed from their former sowing method of "narrow plots with wide and shallow furrows" and promoted the advanced technique of "wide plots with narrow and deep furrows". This not only increased the soil utilization rate, but also lowered the ground water table and avoided disintegration of roots and premature plant deterioration during the late stage. Fuqing County also promoted Jiangjing Commune's experiences in obtaining bumper harvests through the mixing of nitrogenous, phosphate and potash fertilizers in a change from its former habit of overfertilization with nitrogeous fertilizer. This made the barley and wheat stems sturdy, the heads large, and the grains numerous. In addition, ever since the lunar new year both temperatures and quantity of rainfall favored crop growth. As a result, harvest of barley and wheat this year have been particularly bumper. Longhai County's yields reached 320 jin per mu, 50 jin more than last year. At Jiaomei Commune in that county, total output of barley and wheat this year broke 10 million jin for the first time in a 23 percent increase over last year. Shanyou County's yields also reached 320 jin per mu, 30 jin more than last year. All smiles, commune members said, "This year harvesting barley and wheat was like cutting rice; truly such a bumper harvest year has never been seen." However, there were also some commune members who had not grown barley and wheat who said with a sigh, "Had we known that this year's harvest would be this good, we would have listened to what the cadres said in the first place."

MEETING HELD ON EXPERIENCES IN FORESTRY

SK240331 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 23 Jun 82

[Text] The provincial CCP Committee and government held an on-the-spot afforestation meeting in Jingchuan County from 9 to 16 June to introduce the county's experiences in forestry development and discuss ways to accelerate the province's forestry development. Through visits, the participants felt that Jingchuan County had made a heartening start and had set an example in changing the vicious cycle of agricultural production into a good one by attending to agricultural water conservancy and water and soil conservation to improve vegetation instead of merely to water conservancy. At present, the county has basically planted trees along roads and rivers and around houses and villages, built in fledgling form shelterbelts around farmlands, built protective belts along enbankments, scored initial achievements in harnessing small rivers and attained self-sufficiency in sapling supplies. The participants were deeply impressed by the county's achievements in improving the economic results in forestry production, by its spirit of self-reliance and hard work and by its practice of having leaders personally join in tree planting. They thought that Jingchuan County's experiences in afforestation were worth learning from. Having a goal to fight for, they were determined to successfully learn from, apply and publicize the experiences enabling them to achieve results everywhere in the province.

In addition to studying the county's experiences in forestry development, the meeting participants summed up the province's spring afforestation work. They held: Although the province overfulfilled by 14.3 percent its annual afforestation plan, it has done a poor job in sapling nursing and forest protection, which lags behind forestry development. Besides, the province has failed to pay sufficient attention to forestry scientific research and grass planting.

The meeting stressed: Tree and grass planting is a strategic task. Leading cadres should be promoters of turning their sole attention to grain production into dual attention to grain production and a diversified economy and sole attention to water conservancy into dual attention to water and soil conservation and water conservancy to improve vegetation, so as to accelerate afforestation and strive to expel drought from our province.

GANSU

STRENGTHENING OF WINTER WHEAT MANAGEMENT URGED

Lanzhou GANSU RIBAO in Chinese 10 Apr 82 p 1

[Article: "Seize the Opportune Time to Strengthen Winter Wheat Management"]

[Text] Recently, in order to do a good job of reporting on the question of winter wheat production in our province this year, this reporter interviewed responsible comrades of the provincial agricultural department. They said: We are now seizing the opportune time to strengthen winter wheatfield management so as, by every possible means, to wrest a bumper harvest of winter wheat this year.

Question: What is the situation with regard to winter wheat production this year?

Answer: This year our province has a total of nearly 11 million mu planted in winter wheat, or an expansion of more than 1 million over last year's acreage. If we add to this the other winter grains in addition to wheat and rice, the entire acreage of overwintering grain crops is 12 million mu. Due to implementation of the production responsibility system, the enthusiasm of the cadres and masses was aroused, last year's soil moisture was increased, preparations for plowing and sowing were done in a relatively solid manner, the sowing was fairly good, and seedlings have emerged all over the fields. Since the beginning of spring, rain or snow has fallen continuously in eastern and southern Gansu, and the amount of water contained in the plowed layer of wheatfields for the most part is about 20 percent. This good situation in soil moisture has rarely been obtained in the past several years. At present, the winter wheat has already turned green, most of the sprouts are in good condition, and in many places the young wheat plants are growing healthily and strongly. For example, there are the results of a general survey of the over 858,000 mu of young winter wheat seedlings sown this year in Wudu Prefecture: first-category seedlings accounted for 40 percent, second-category 44 percent and third-category 16 percent. Compared with the corresponding period of last year, the acreage of third-category seedlings was reduced by 20 percent.

Question: What problems are there in this year's winter wheat production?

Answer: From our present understanding of the situation, the several main problems existing in this year's winter wheat production are as follows: First, in some places in eastern Gansu and west of the [Wei] River, from the first part of October to the first part of November last year temperatures tended to be low as if winter had come 7 to 10 days earlier than normal, which caused the winter wheat to have insufficiently warm temperatures before winter actually began. The growing period was shortened, particularly for some rotation-crop wheat that had been sown late when planting had been expanded, so that everywhere the growth of the crop was slow, there was little tillering and secondary roots, and the wheat seedlings grew fairly weakly. According to an investigation made by the Agricultural Department of Qingyang Prefecture, the primary and rotational wheat timely sown in the middle of September on the average had two to three tillers before winter, about three less than in previous years; the wheat seedlings planted late, at the end of September or afterward, both primary and secondary, were thin and weak with very few tillers and secondary roots, and some even had none. Second, in areas of southern Gansu wheat rust, and in some areas wheat aphid, leafhoppers and planthoppers, occurred in succession and harmed the crop. According to an investigation made by the Agricultural Department of Wenxian County, winter wheat rust has already begun to spread: On 10,000 mu, the general proportion of highly affected strains has reached 40 percent--in specific places 100 percent of the wheat has caught the disease--and on the average 25 percent of the crop has been affected to a serious degree. It is estimated that in the first part of May the disease will have spread to the Wei River basin. By the middle and last parts of May, it will have spread to eastern Gansu and the central areas, and this should draw our attention to a high degree. Third, in some places, because there was much rainwater the soil moisture content is high, so that in the wheatfields weeds have multiplied and spread, competing with the wheat seedlings for water and fertilizer, which is extremely detrimental to the healthy and sturdy growth of winter wheat. Fourth, in some places, because last autumn was excessively overcast and rainy, the accumulation and shipment of fertilizer was adversely affected, and there was insufficient base fertilizer in the wheatfields, and in a small number of wheatfields the seeds were even planted during rain, so that the strengthening of field management and other measures is urgently needed in order to promote the healthy and sturdy growth of wheat seedlings. Moreover, looking at the situation in our province over the years, there is a big threat to wheat growth posed by freeze damage from a late frost, and we should watch out for this closely.

Question: What measures must be taken now to do a good job in wheatfield management?

Answer: At present, winter wheat in the plains of eastern and southern Gansu has already entered the jointing stage, and winter wheat in the mountain and plateau areas as well as the large acreage in the central areas and the areas west of the Wei River is now in the greening and sprouting stage. All these places should focus on their weak links, take effective measures, and strengthen field management.

First, for wheatfields that have not yet sprouted, the peasants should continue to topdress and expand the area on which fertilizer is applied, especially on those wheatfields where the base fertilizer is insufficient or where seeds were sown in the rain, and they must especially topdress and apply chemical fertilizer so as to do all they can to topdress all wheatfields once before the jointing of winter wheat begins. In places where the necessary conditions exist, irrigation and fertilizer application should be combined, and in wheatfields running to weeds or with a high moisture content, timely loosening of soil and weeding should be carried out and temperatures should be increased to preserve soil moisture, all of which will promote the development of root systems and insure the sturdy growth of wheat seedlings.

Second, the management must be classified according to the condition of the seedlings. Weak seedlings and rotational-crop wheat must receive favored treatment. With regard to wheat seedlings that are growing luxuriantly, the water and fertilizer should be controlled, and such measures as timely rolling and cycocel spraying should be taken so that the seedlings are controlled but not weakened, grow vigorously but do not topple over. Practice has proved that an effective measure to increase wheat output is to spray the leaves of the wheat plant in the latter stage of its growth with potassium dihydrogenphosphate. Various places may suit measures to local conditions, energetically propagate the measures, and work hard for large and plump ears on and high output of winter wheat.

Third, in order to strengthen the prevention and control of plant diseases and insect pests, they must conscientiously do a good job of preestimating and forecasting plant diseases and insect pests, and handle well the "two checks and two fixes" (check on the course of outbreaks and fix times for prevention and control; check on the number of outbreaks of plant diseases and insect pests and fix plots on which to carry out prevention and control). The southern part of our province usffers much from wheat rust, which has already begun to spread. We must organize our forces and take effective measures to quickly stamp it out and prevent its spread. A specific method for prevention and control is: Under the premise of undertaking good prevention and control in agriculture, one should pay attention to eliminating the source of the bacteria that causes early spring rust, and spray on every mu a liquid agent composed of 1 percent sulfur ammonia water, or one part fresh water to one part urine, or 3 percent ammonia water, and 100 grams of sodium fluorosilicate in order to control the center of the disease. During the period when the rust is spreading and 1 percent of the leaves are diseased, in the initial period the leaves can be sprayed with 0.5 to 0.8 degrees of lime sulfur, or each mu can be sprayed with 3 to 4 jin of sulfur poweder, or each mu can be sprayed with half a jin of rust-resistant sodium liquid agent, or with 200 grams of bacteria-destroying powder made into a liquid agent. As for insect pests, such as wheat aphid, leafhopper, planthopper and wheat waterfly, they can be sprayed with emulsified Rogor, 50 grams per mu when added to water to form a liquid agent; or sprayed with DDVP and malathion or xinliulin [6580 4288 4340]--they are all highly effective. For the specific methods of preparing and using the agricultural chemicals, the various areas can request guidance from the scientific and technical personnel of the agrotechnical plant protection departments.

Fourth, prevent freeze damage from a late frost. The fundamental freeze-prevention measures are the selection of freeze-resistant strains, the strengthening of field management, and the cultivation of sturdy seedlings. For this the various areas have some specific methods, and they should pay close attention to the forecasts of the local meteorological departments, adopt measures suited to local conditions and protect the wheat by preventing freezing.

Finally the responsible comrades of the provincial agriculture department emphatically pointed out: Looking at the present situation, this year's weather will be comparatively good, which will be extremely advantageous for the growth of winter wheat. But we certainly cannot lower our guard and become careless, be blindly optimistic, and treat the situation lightly with regard to obtaining a bumper harvest of winter wheat. We must still put in a lot of hard work and get a tight grip on wheatfield management in order to strive hard for a bumper harvest of winter wheat.

PREVENTION OF WHEAT MIDGE BEGUN

Lanzhou GANSU RIBAO in Chinese 15 Apr 82 p 2

[Article by Li Cheng [2621 2052]: "Prevention and Control of Wheat Midge"]

[Text] Based on the serious harm done by the wheat midge over the past several years in the Hedong Production Brigade, Hetan Commune, Dongxiang Autonomous County, the production brigade, during this year's spring plowing and production, signed a contract with the Plant Protection Station of Linxia Autonomous Prefecture for the active prevention and control of the wheat midge. Since the production brigade put into practice the production responsibility system of contracting production to households 2 years ago, because the contracting households lacked the strength for prevention and control on connected strips of land and the brigade did not organize the masses very well for this purpose, the midge infestation has become quite serious. In 1981, on 1,000-odd mu of wheat there was a steep drop in production. The masses urgently requested help from the agriculture technology departments. In line with the masses' request, the Plant Protection Station of Linxia Autonomous Prefecture and the Agrotechnical Station of Dongxiang Autonomous County, with production teams, signed plant protection technology contracts linked to output. Under the terms of the contracts, the technical departments are responsible for presurveying and forecasting the midge situation, for training technicians for the production teams, and for supplying agricultural chemicals and maintaining machinery, and if crop damage occurs from the use of the agricultural chemicals or if the prevention and control measures are ineffective and production falls, the technical departments will make up for the loss of output; the production teams must respect the technical guidance, are responsible for organizing and leading the contracting households, and shoulder the expenses.

Prevention and control has been carried out once by the production brigade on 2,500 mu of the 2,800 mu of wheat acreage, and a second round of prevention and control will be carried out when the wheat is in the earing and milking stage, so that midge damage can be basically avoided. The cadres and commune members are generally satisfied with this contract system. The sense of responsibility for work on the part of agrotechnical cadres has been greatly strengthened, and they have gone into the fields and to the edges of the fields in time to get a good idea of the midge situation and to guide the masses in scientifically tilling the land.

QINGYANG PREFECTURE WINTER WHEAT MANAGEMENT STRENGTHENED

Lanzhou GANSU RIBAO in Chinese 15 Apr 82 p 2

[Article by Gong Shifeng [0501 0013 6912]: "Qingyang Prefecture Strengthens Winter Wheatfield Management"]

[Text] In Qingyang Prefecture, the vast rural areas have got a tight grip on spring field management of winter wheat and are determined to wrest a bumper harvest of wheat this year.

In Qingyang Prefecture, since spring began, because there has been a fairly large amount of snow and rain and temperatures have been inclined to be low, there exists widespread detrimental factors for the wheat, such as little tillering, small colonies and rather poor seedling conditions. Throughout the prefecture, the communes and production teams focused their wheatfield management on the problems that had appeared and first of all applied chemical fertilizer with drill barrows. Once the ground had thawed, the commune members went into action. In places where animal power was insufficient, kinsmen and neighbors helped each other to do the work; in places that were short of drill barrows, the commune members exchanged draft animals so that the drill barrows did not stop working and the tempo of the work was quickened. As of now, throughout the prefecture chemical fertilizer in drill barrows has been applied to over 1.84 million mu, or more than 80 percent of the planned acreage. Second, they intertilled and dug up weeds with hoes. Some communes and production teams on flat land in the counties of Ningxian, Heshui, Zhengning and Zhenyuan, where the weather has been fairly mild, have begun to intertill and to hoe weeds. Some production teams on flat land in the Chengguan Commune of Ningxian County have already completed two hoe-weedings. Third, they have timely prevented and controlled wheat rust, wheat aphid, red spider mite and other plant diseases and insect pests. Throughout the prefecture many commune members' households have prepared adequate amounts of plant ash, and some households of communes and production teams on the Qian Plateau have already sprinkled plant ash on the wheat land. The greater part of the communes and production teams have purchased agricultural chemicals and have made preparations to prevent and control diseases and insect pests that affect wheat.

INCREASED USE OF PLASTIC FILMS IN AGRICULTURE IN GANSU

Lanzhou GANSU RIBAO in Chinese 24 Apr 82 p 1

[Article by GANSU RIBAO correspondent: "Plastic Mulch Acreage Nearly Doubled in Jiuchuan Prefecture--Popularization of Last Year's Experiments Welcomed This Spring"]

[Text] From the experiments conducted at 18 different locations last year, the broad masses of cadres and commune members have witnessed the economic results from the use of plastic films for the crops. This spring, the relevant departments in the prefecture and the county popularized this method, which was warmly welcomed. By now, the plastic mulch acreage in the prefecture has been increased to more than 4,800 mu, or more than 32 times the experimental acreage.

Last year, the county (municipal) stations for the popularization of agrotechniques in Jiuquan Prefecture planted cotton, watermelons, cucumbers, bailan melons, bottle gourds, beans and so forth, under the cover of plastic films, at 18 experimental spots, totaling 146 mu. Except for a small number of failures caused by typhoons, most of these experiments resulted in greatly increased outputs. At the three experimental spots in Dunhuang County, the average per-mu output of cotton was 267 jin and 4 liang. In the county fine-strain farm, where 4 mu was covered by plastic films for the production of bailan melons, the average weight of each melon was 4.5-5 jin, with the heaviest one at 6 jin and 8 liang. The average per-mu output was more than 5,000 jin, a 67 percent increase over the yield with the uncovered method, meaning an additional income of 168 yuan.

Early last March, after summing up and exchanging experiences in last year's experiments, the Jiuguan prefectural and county agrotechnical stations discussed their plans for expanding the plastic mulch acreage. Then the county (municipal) agrotechnical stations signed a number of contracts with the communes and production brigades on the combination of technology and production. According to statistics available in mid-March, all the communes, production brigades, county horticultural farms, and fine strain farms in the prefecture had already bought more than 48 tons of plastic films, while Dunhuang, Xian and Jinta counties planned to cover nearly 1,000 mu of cotton with plastic films. Many communes and production brigades are still buying plastic films to be used on various types of melons and vegetables in addition to the 3,500-odd mu already covered. It is estimated that the total acreage may exceed 5,000 mu.

PLANTING OF SAFFLOWERS WIDELY POPULARIZED IN GANSU

Lanzhou GANSU RIBAO in Chinese 21 Apr 82 p 1

[Article by GANSU RIBAO correspondent: "Planting of Safflowers for Oil Extraction Widely Popularized in Zhangye Prefecture"]

[Text] After nearly 2 years' demonstration at designated spots, the planting of safflowers for oil extraction is now widely popularized in Zhangye Prefecture. At present, more than 800 mu has been planted with safflowers, and sowing has continued since early April.

The safflower is valuable as a cash crop because of its oil and flower petals. Among its special features are its high output, its high percentage of oil content, and its wide range of utility. Besides being edible, it has high medicinal value and is an important industrial raw material. Its stems contain a great deal of albumen and are excellent fodders for domestic animals. Zhangye Prefecture has favorable conditions for planting safflowers because of its dry climate, large temperature fluctuations and abundant sunlight. Furthermore, the people here have been all along fond of, and are experienced in, planting safflowers. In 1980, the botany institute of the Chinese Academy of Sciences designated Zhangye Prefecture as one of the main safflower production areas of the country, and the prefectural agriculture institute undertook the task of nurturing and propagating safflowers. These institutes have on different occasions brought in from Beijing more than 60 fine varieties of safflowers of American, Mexican and domestic origins, and planted them at different designated spots in the irrigated and the high and cold mountainous areas. They achieved fairly good results after 2 years' experiments. Last year, more than 170 mu was planted with safflowers in the prefecture. The highest per-mu output was 500 jin, and the lowest was 300, with an oil extraction rate of approximately 40 percent. This year, in addition to those areas in state farms and communes and production brigades, nearly 500 mu along the banks and on the deserted beaches was used by the commune members for planting safflowers.

BRIEFS

GANSU SPRING WHEAT SOWING--According to data supplied by the agricultural departments in the province, sowing for spring wheat and miscellaneous summer crops has been basically completed over an area of 14 million mu, an increase of 2 million mu over last year, in the countryside of the province, according to this year's plan. All rural areas are more practical in their farming preparations this year; thus the sowing was timely and its quality is good. Sowing for spring wheat was completed by the end of March in Jinta County, Dunhuang County, the various counties in the Heihe irrigated area, the Jingdian irrigated area, the Shiyanghe irrigated area, and the Lintaochuan irrigated area. EXPERIMENTAL WATER DESALINIZATION PLANT--Lanzhou, 29 Jun (XINHUA)--China's first experimental water desalinization plant will be built on the banks of the Yellow River in Lanzhou, capital city of Gansu Province, according to the Gansu Provincial Academy of Sciences here today. The plant will help assess water desalinization methods applicable to China. More than 100 million people in China live in areas with saline or alkaline water, academy sources said. The pilot plant will process 1,000 tons of alkaline water daily. Started in 1980, its major buildings will be completed this year. [Text] [OW010453 Beijing XINHUA in English 0725 GMT 29 Jun 82 OW]

IMPROVED FOREST MANAGEMENT REPORTED

Guangzhou NANFANG RIBAO in Chinese 11 May 82 p 1

[Article: "Timber Procurement in Province During First 4 Months Increased By More Than 10 Percent Over Same Period Last Year. Implementation of Timber Production Policies and Strengthening of State Plan Concepts"]

[Text] Following the practice in all prefectures of the province of centralized administration and management of timber, initial successes have been realized in the strengthening of state plan concepts, early institution of this year's timber plan quotas, and active launching of contract agreements for procurement work. Statistics show that during the first 4 months of this year, quantity of timber procurement for the province amounted to 533,000 cubic meters, a 10.9 percent increase over the same period last year.

Because of the influence of "leftist" mentality, inconsistency in mountain forest ownership rights, and turmoil in forest area production for many years, state plan concepts and legal concepts of numerous cadres and commune members became increasingly diluted, and reckless cutting and denudation of forests, plus meddling in timber administration by many parties could not be stopped. This led to the province being unable to fulfill its state timber quotas for 4 consecutive years.

Since last year, all jurisdictions in the province have implemented the Central Committee and State Council "Decisions on Various Problems Relating to Forest Protection and Development," and have taken firmly in hand the "three fixed" tasks in forestry. They have diligently put into effect the central government and provincial government decisions and methods of implementation pertaining to centralized and unified management of timber. With this, most forest region communes and brigades in the province have regularized forest and mountain rights, and the tumultuous situation of multiple administration and management of timber has been corrected. Most prefectures and counties have virtually put an end to reckless cutting and denudation of forests. They have closed down the free market in timber, have struck at speculation and profiteering in timber and have brought order to forestry production in forest areas to assure the normal production and supply of timber. After all forest areas in Huiyang Prefecture instituted centralized administration and management of timber, the signing of contract agreements for timber procurement proceeded smoothly. Quantity of timber procured during the first 4 months of this year was more than 37,000 cubic meters more than for the same period last year. Xingning County investigated and disposed of a group of cases involving reckless cutting and denudation of mountain forests, attacked violators, brought order to production, and during the first 4 months of this year provided the state with more than twice as much timber as during the same period last year.

In the process of instituting centralized administration and management of timber, forest areas in all jurisdictions diligently put into effect various specific policies pertaining to timber production and management. They set the rights, responsibilities, and beneifts for all counties, communes, brigades, commune members, and administrative units involved in the production of timber so that they would produce timber in accordance with state plans. In addition, state readjustment of timber prices brought material benefits to the masses in forest areas throughout the province. This played a positive role in arousing the enthusiasm of the masses in forest areas for the production of timber and in assuring fulfillment of state procurement plans.

Timber is an important material in national construction and the livelihood of the people. In the current situation of a scarcity of forests, if forest resources are to be effectively protected and rationally used, centralized and unified management of timber is completely necessary in order to change the chaotic situation of the past in which there was multiple management and multiple meddling, "forests being created with a single hoe and trees being cut down with 100 axes." While implementing the "three fixeds" in forestry this year, all forest areas have strengthened centralized management of timber. The substantial increase in timber procurement throughout the province during the first 4 months of the year provides powerful testimony to this.

Deserving of attention is the failure of individual places to proceed from the overall situation, wilfully increasing timbering outside of plan. In some places, most of the timber procured is retained for local use, very little of it being surrendered to the state. Alternatively, they keep the large timber of good quality, surrendering to the state small timber of inferior quality. This is a manifestation in the economic realm of selfish departmentalism and decentralism, which should be resolutely corrected. In still other places, because policies have not been implemented and concepts of law are weak, a rather serious situation of reckless cutting and denudation of mountain forests continues to exist, and this too requires effective action to bring it to a halt.

CONTROL OF RICE DISEASES DISCUSSED

Guangzhou NANFANG RIBAO in Chinese 24 Apr 82 p 2

[Article: "Need for Strong Action To Prevent and Control Rice Blast"]

[Text] Provincial Academy of Agricultural Sciences plant protection experts believe that rice blast will be rather serious in Guangdong Province this year. The evidence is as follows: 1) Last year rice blast occurred on 4 million mu throughout the province, and there is a large accumulation of bacteria sources. 2) During the seedling propagation season this year, temperatures tended to be low, and everywhere seedling quality has been rather poor; this helps the spread of bacteria. 3) Most early rice varieties being promoted are disease-prone varieties. 4) In recent years fertilization has increased everywhere, nitrogenous fertilizer being particularly ample. 5) Rice leaf-blast disease has broken out everywhere among early crop seedlings. Monitoring reports from provincial crop disease and insect pest monitoring and reporting stations tell of the occurrence of rice leaf-blast disease in seedling fields in Panyu, Huaxian, Taishan, Xinhui, Meixian, Wuhua, Jiaoling, and Yangjiang counties, and it has now gone into the open fields. A similar situation exists elsewhere throughout the province. Unless timely preventive measures are taken, rice-leaf-blast will develop further during April and May. By early or mid-June, if there is a lot of rainfall, outbreaks of rice neck blast will be fairly serious.

In order to prevent and control rice blast, emphasis on scientific fertilizer and water management is necessary right now to increase the rice plants' resistance to disease. In fertilizing, the principle of "heavy early" (within 20 days after transplanting), "late light" (40 days after transplanting when the yellowness has faded from the plants), and "nothing or supplemental in the middle" (between 20 and 40 days after transplanting) should be followed. Even fertilization on time and in the right amounts should be done according to weather conditions, soil conditions, and the condition of plants, and one should remember to give a little nitrogen fertilizer during the mid season. During the jointing and differentiation period, the fields should be promptly drained of water, sunned, and exposed to the air so that leaf color will "yellow" normally, so as to control or reduce the incidence of leaf-blast. Five or 6 days before heading, fields should be drained and exposed to the air again to bring about the second "yellowing" for the control or decrease of rice neck blast and stem node blast.

Simultaneously with scientific fertilizer and water management should be an intensification of field inspections to determine the disease situation and promptly apply pesticide for prevention and control. Generally, beginning with the tillering stage it is necessary to spray pesticide once or twice to prevent or control leaf blast. Centers of disease outbreaks must be more intensively controlled with sprayings once every 3 or 4 days. Later on between the late booting stage and the onset of heading, spraying should be done once, and after full heading spraying should be done once again to prevent and control rice neck blast. Because the period of disease susceptibility is fairly long during the heading stage, another spraying during the in-the-milk stage would be even better.

All areas report that current use of "EBP" is not very effective in the prevention and control of disease. This may be the result of pesticide quality or because, after much use, the diseases have increased their immunity to the pesticide. Therefore, quantities of pesticide should be in reased, spraying done with a solution of 3 liang per 120 - 140 jin of water per mu. Additionally, depending on circumstances, each jurisdiction may select for use the following concoctions: 50 percent carbendaxol miscible powder dissolved at a rate of 2 liang per 120 - 140 jin per mu, or 50 percent Tuobujin [2094 1580 3160] miscible powder dissolved at a rate of 2 liang per 120 - 140 jin of water per mu, or 40 percent edinphensoph emulsion dissolved at a rate of 2 liang per 150 jin of water per mu, which can be used for the simultaneous control of rice leaf hoppers.

LEAN MEAT HOG RAISING BOOSTED

Guangzhou GUANGZHOU RIBAO in Chinese 10 May 82 p 1

[Article: "Guangzhou's Fine Breed Hog Farms Become Breeding Centers for Lean Pork Hogs. Pork From This Breed of Hogs Accounts for More Than 65 Percent of Total"]

[Text] Guangzhou Municipality's fine breed hog farms have begun to take shape as purebreed hog breeding centers for lean pork hogs. They have also provided the municipality, the province, and other provinces with 136 head of purebred lean pork boars and a large quantity of fine breed hog semen to make a contribution to the breeding and promotion of lean pork hogs.

In order to satisfy popular demand in the municipality for lean pork, in October 1978 the Municipal Agriculture Bureau began operation of the Guangzhou Municipal Fine Breed Hog Farm in the foothills of Rentouling at Taihe Commune in Guangzhou's northern suburbs. When the farm was established, several patriots from industrial and commercial circles in Hong Kong subscribed HK$300,000 for joint partnership, and imported 96 head of fine breed lean pork hog varieties from the United Kingdom. Breeds imported were Durocs, Hampshires, Landraces, and British Large Whites. Now these four fine breeds have grown to number more than 300 head. Taken together with other fine hybrid hog varieties, the number being raised totals more than 500 head. The farm has built 13 hog housing facilities of farily advanced design on an area of more than 4,000 square meters. The entire production flow has been made a continuous process, and a full range of scientific instruments and equipment exists, the only such in the country. There are four fine variety foreign purebreed lean pork hog breed farms. During the past few years, Guangzhou Municipality's fine variety hog farms have provided the municipality, the province, and other provinces with 130 fine variety purebred boars and large quantities of fine variety hog semen, and have also provided fine variety hog semen free of charge to hog raising farms in Shahe, Jiangcun, and Renhe communes in the municipality's suburbs. They have helped these communes train technicians and to carry out comprehensive hybrid experiments. All jurisdictions have achieved preliminary successes in the hybrid experiments they have conducted using fine variety purebreed hogs and fine variety hog semen provided by Guangzhou Municipality's fine variety hog farms. The proportion of lean pork from hybrid hogs averages more than 10 percent more than that obtained from local hog varieties.

The aforementioned four fine variety lean pork purebred hogs that the Guangzhou fine variety hog farm introduced from the United Kingdom have three noteworthy characteristics: One is much lean pork, lean pork amounting to more than 65 percent of total pork, about one-third more than the lean pork obtained from local hogs. The second is rapid growth and development, an increase of more than 40 jin per month taking place during the period of maximum growth. Within 6 months after birth, weight may reach more than 180 jin. The third is a high rate of feed conversion to meat, an average 1 jin of meat developing from every 3 jin of feed consumed.

In addition to working hard at breeding and providing other places with lean prok purebred boars and fine variety hog semen in 1980, the Guangzhou Municipal fine breed hog farm began observation of binary hybridization experiments, namely the corssbreeding of "Duroc" and "Hampshire" purebreed boars with local "Large Spotted White" sows. Hybrid progeny grow meat faster than local hog varieites; they have good body shape; and the rate of feed conversion to meat is high. The lean pork ratio is also 10 percent higher than that of local hog breeds. In order to achieve even higher targets, beginning last year they initiated trinary hybridization experiments. Currently the first group of trinary hybrid hogs are in process of being evaluated.

RICEFIELD CARE METHODS EXPLORED AT CONFERENCE

Guangzhou NANFANG RIBAO in Chinese 24 Apr 82 p 1

[Article: "Field Care Intensified in Light of This Year's Characteristics. Agricultural Experts Give Counsel and Contribute Plans To Win Bumper Harvest From Early Crop. Emphasis Given Sensible Fertilization, Scientific Use of Water and Doing a Good Job of Disease Prevention and Countering Disasters"]

[Text] At the symposium for fertilizing techniques recently convened in Guangzhou, numerous agricultural experts put forward suggestions as to how to intensify field care to win bumper harvests from the early crop.

In analyzing the current early rice production situation, the experts noted that: during this year's farming, with the exception of Hainan Island, the time of transplanting seedlings throughout the province was fairly concentrated, which was helpful to field care. Supplies of agricultural means of production such as chemical fertilizers and pesticides were also rather good. However, problems were also numerous. One was the lateness of the season, transplanting of seedlings which ended about 7 days later than in former years. Second was poor seedling quality. Seedlings grown in some areas around the fields were dwarfed, old, weak or yellow. In mountain and hill areas, seedlings were tender, closely planted, and weak, and in some places too many seedlings were transplanted in a cluster. Third, in some places organic fertilizer was fairly scarce. Fourth, following transplanting, seedlings greened up slowly and tillering was delayed because of the weather. Fifth, damage from diseases, insect pests, and rats was fairly severe. Sixth, rainstorms and typhoons were fairly frequent this year. The first typhoon came early, posing a threat to flowering of the early rice crop. Consequently, the task of winning increased yields from the early rice crop will be a rather arduous one.

In order to win a bumper early rice crop harvest, the experts believed that: the overall guiding mentality must be the adaptation of general methods to specific situations, tailored guidance, attention to special characteristics, seeking high yields in intermediate yield areas, and bracing oneself to fight diseases and disasters to win a bumper harvest. Among specific actions to be taken, attention should go to the following several links:

(1) Sensible use of fertilizer. There should be no indiscriminate use of nitrogenous fertilizer, and increased use of phosphate and potash fertilizers should be energetically advocated in order to increase plant resistance.

The principles of fertilization should be flexibly applied in accordance with different soil, weather, variety, and seedling growth conditions. In order to avoid bolting of seedlings in midseason, the following criteria should be adhered to: First is that for conventional varieties, the number of tillers per mu should be controlled at 200,000 to 250,000; for hybrid varieties, they should be controlled at around 200,000. Second is at the end of April and no later than "summer begins" [around 5 May], no matter whether or not there are sufficient seedlings, the seedlings have to be controlled through rapid exposure and sunning of the fields.

(2) Maintenance of scientific use of water. First is a change during the early stage of seedling growth from deep irrigation and slow irrigation to cutting back on stagnant water and use of shallow water wetting, exposing the fields from time to time in order to increase soil temperature, increase oxygen, and vitalize the root system. Second is a change from delayed seedling sunning and heavy sunning during the midseason of seedling growth to early field exposure, early sunning, much field exposure and light sunning depending on different circumstances, to promote deep rooting of seedlings in order to increase resistance. Third is a change from long irrigation or drying up with yellow maturing during the late stage of seedling growth to moistening irrigation and much irrigation with running water to prevent black root and premature ripening from high temperatures.

(3) Attention to prevention and control of disease, insect pest, and rat damage. Disease, insect pest, and rat damage for the province as a whole this year has been forecast to be as serious as last year. The threat is fairly great from blast of rice, sheath and culm blight, bacterial blight, leaf hoppers and rat damage, particularly early outbreaks of blast of rice causing widespread damage.

This conference was convened by the Guangdong Provincial and Guangzhou Municipal Oil and Grain Crop Society. Delegates to the conference totaled 45 and included high and middle rank agronomists and technicians from the province and Guangzhou Municipality as well as from some prefectures.

BRIEFS

FURTHER ON TYPHOON NO 5--The Central Meteorological Observatory issued a typhoon warning at 0600 [2200 GMT] on the morning of 30 June. The center of this year's No 5 typhoon moved to sea areas approximately 150 kilometers south of Yangjiang in Guangdong Province at 0500 [2100 GMT] this morning, that is, 20.4 degrees north latitude and 112.0 degrees east longitude. Maximum wind near the center of the typhoon ranges from force 8 to 9. The center of the typhoon is now moving in a northerly direction at about 10 kilometers per hour and is expected to continue its northerly movement, gradually approaching the coastal areas of western Guangdong. It is expected to cross the coastal areas sometime this afternoon or evening. Due to the typhoon, the sea areas in the northern part of the South China Sea and coastal areas of Guangdong will experience strong winds of force 6 to 8 during the daytime and night today. Areas along the path of the center of the typhoon will experience strong winds of force 8 to 9. Heavy or torrential rains are expected in the coastal areas of Guangxi and Guangdong and on Hainan Island. All units concerned, please pay attention to weather forecasts by local meteorological stations. [Text] [OW300644 Beijing Domestic Service in Mandarin 2230 GMT 29 Jun 82]

PRODUCTION INCREASES--All places in Hainan administrative region have seriously implemented the State Council's directive on speeding up the exploitation and construction of the region. The region increased agricultural, forestry, livestock, sideline and fishery production in the first half of this year. The region's early-rice output this year was nearly 10 percent more than in the corresponding period of last year. Compared with the first half of last year, output of sugarcane increased by some 50 percent, output of peanuts and pineapples each increased by some 40 percent, output of dry rubber increased by over 10 percent and output of coffee, lemongrass, tea and pepper increased by some 20 percent. Since the second half of 1980, leadership organs at all levels of the party and the government in the region have conducted investigation of agricultural resources, formulated plans for agriculture and readjusted production arrangements. The region now has about 6.1 million mu of paddy rice-sown fields and has cultivated sugarcane and other industrial crops on 300,000 mu of low-yielding dry fields. The region has cultivated tropical industrial crops, with rubber as the main product, in mountainous areas, hilly land and slopes. The region has vigorously developed windbreak forest belts along the coastal areas. The region has made full use of barren mountains and slopes to develop the breeding of cattle and goats. The region has also developed the production of aquatic products in ponds, lakes, reservoirs and the sea. [HK011117 Haikou Hainian Island Service in Mandarin 0330 GMT 30 Jun 82]

'HEBEI RIBAO' COMMENTS ON RURAL WORK TASKS

HK250122 Shijiazhuang HEBEI RIBAO in Chinese 18 Jun 82 p 1

[Editorial: "We Should Concentrate on Tackling Three Tasks in Rural Work"]

[Excerpts] What are the main tasks to be tackled in rural work? This is a major topic that should be frequently studied by the leadership at all levels. By discovering and tackling the main issues in rural work and seriously acting to solve them, we can stimulate the unfolding of all rural work and get twice the result with half the effort. Otherwise, if we tackle everything at the same time without drawing up the priorities, we will not be able to achieve the result we should.

What then are the main tasks to be tackled in the rural areas at present and for a time to come? Generally speaking, as in other work, we should concentrate on building the two civilizations. This is the general demand. To put it specifically, there are three main things to be tackled: Vigorously developing agricultural production; unwearyingly working to perfect, enhance and consolidate the production responsibility systems; and strengthening the leadership of the rural party branches and carrying out organizational rectification of them. These three tasks are the three cardinal links in rural work; they are closely linked together and inseparable. Developing production is the aim of setting up the production responsibility systems and the material basis of consolidating these systems; further perfecting the production responsibility systems is the source of promoting the rapid development of production; and strengthening the leadership of the party branches and rectifying the party's organization is the main guarantee for fulfilling the other two tasks. We have done a lot of work in this respect since last year. In particular, notable achievements have been scored in setting up and perfecting the production responsibility systems. Only some areas in Hebei set up these systems before 1981, and very few units set up the system linking remuneration to output. Now almost all the province's 126,000 basic accounting units have set up production responsibility systems. Thanks to the establishment and perfection of these systems, the previously unsuitable production relations have been readjusted and the development of productive force has been greatly stimulated. The province reaped a good harvest last year despite serious drought. The rural areas are not politically stable and united, the peasants' socialist enthusiasm has surged up to an unprecedented extent, production has developed very fast, and there are extensive avenues for producing wealth. Not only have the majority of places solved the problems of adequate food and clothing; in addition, a number of peasant households and communes and brigades that have become rich ahead of others have appeared. The rural situation is indeed very good. Our party organizations and the party members have also been made stronger amid the readjustment of production relations and the practice of production. Last July and August, conditions of paralysis or semi-paralysis appeared on 20 to 30 percent of the production brigades in the province, but now the problems have in most cases been solved. Only 1 or 2 percent have yet to solve their problems, and in most cases these were caused by historical factors. The proportion of first and second-category grassroots party branches has increased, while that of third-category ones has declined. Of course this does not mean that we no longer have any problems. The problems still exist. As far as developing production is concerned, there are still many problems that need solving; and one of the major problems is that of emancipating the mind. First we must carry out emancipation in production relations; organizing responsibility systems represents emancipation in the production relations. Second we must emancipate ourselves from the bindings of simply growing grain and nothing else, and promote diversification. We have still not sufficiently emancipated our minds in this respect. Third, we must emancipate ourselves from old-fashioned and backward cultivation methods and vigorously promote scientific cultivation. At present we have not done too well in this aspect of emancipation. As far as the production responsibility systems are concerned, last year the provincial CCP Committee stipulated eight tasks for perfecting the systems, and the majority of these have now been fulfilled. Some of these tasks still need to be done, in connection with production. As for strengthening the leadership of the party branches and rectifying the party's organizations, it is all the more necessary to devote great effort to this task. We must therefore continue to get a good grasp of this work.

Developing production, perfecting the responsibility systems and strengthening the leadership of the party branches are closely linked and inseparable tasks. However, they each have their own characteristics. In developing production, we need not only to get a good grasp of current production but also to promote long-term and fundamental construction work. There are three main aspects to be grasped here. First, we must implement the guiding principle of comprehensively harnessing the land, the waters and the forests, with the land in first place. Hebei is on the Loess Plateau and suffers drought 9 years out of 10. We have to fundamentally change the agricultural production conditions. We must work hard to level the land and carry out deep plowing, and do a thoroughly sound and effective job in building the farmland ourself. This is for the following reasons: Large areas of the province's farmland can be deep-plowed; the area of resisting drought and preserving soil moisture is also extensive; not much investment is needed and results are rapid; and both the collectives and the individuals can carry out this work. If we are determined, a great transformation can occur in 2 or 3 years, or 4 or 5 years at the most. At the same time we must pay attention to water conservation and forestry development. Second, we must extensively promote diversification, rationally readjust and straighten out the existing items in diversification and develop new items. We must vigorously develop households that become rich through hard work (specialized households and key households). This is an affair with a great future. These households should be a bridge for leading forward all the peasant households, so as to gradually make agricultural production specialized and enable the peasants to get rich as quickly as possible. Third, we must promote scientific cultivation and strive to achieve major breakthroughs in 2 or 3 years in finestrain seed, plant protection and rational cultivation. In perfecting the agricultural production responsibility systems, we must, in guiding ideology, first establish the idea of building these systems for a long time. On the one hand we are thus drawing the historical lesson from the failure to carry out stabilization, consolidation and enhancement after the establishment of the cooperatives, and on the other it is a practical requirement. Specifically, we must grasp the following aspects: 1) Continue to conduct deep-going socialist education for the peasants in "keeping two things unchanged for a long time." "Taking simultaneous account of the interests of three parties," and "warmly loving four things;" 2) Correctly handle the relations between the state, the collective and the individual. We must lay particular stress on subordinating ourselves to the state's interests, uphold the interests of the collective, and put the state's interests in the first place. This is an issue the peasants must pay attention to solving after gaining their proper decisionmaking powers; 3) Continue to correctly handle the relationship between centralized control and individual responsibility. Last year we paid more attention to individual responsibility, and this was correct and in accord with the actual situation. Now we must pay more attention to the aspect of centralized control. This is an aspect we must stress solving after putting individual responsibilities on a sound basis; 4) We must do well in setting up the responsibility contracts. This is the concentrated expression of correctly taking simultaneous account of the interests of the state, the collective and the individual, and we must also ensure that the contracts are fulfilled; 5) Carry out extensive and penetrating investigation and study, and continually discover and solve new problems and contradictions that crop up in the responsibility systems. In strengthening the leadership of the rural party branches and carrying out rectification of the party organizations, we must this year concentrate efforts on solving the problems of the roughly 15 percent of branches that are backward. Large numbers of cadres have already been sent to the rural areas. We hope that they will score achievements and gain experience.

The rural tasks are heavy, and at present everyone is very busy with the summer farmwork tasks. The key to fulfilling our tasks well lies in improvement of work methods and style by the party committees and cadres at all levels. In the past our work was done mainly in the production teams, but now we must carry out specific work regarding the peasant households in addition to the production teams. The leading comrades in many parts of the rural areas have set up ties with specific households, and by helping them to develop production and get rich through hard work they can lead still more people forward and progress from the enrichment of some to the enrichment of everyone. This is a specific expression of the party's mass line work method of from the masses, to the masses. Every comrade engaged in rural work must do this. In short, we must ensure that our work meets the new situation following the readjustment of the production relations, stimulate all rural work and do still better in agricultural production.

COTTON SOWING REPORTED WELL UNDERWAY IN HEBEI

Shijiazhuang HEBEI RIBAO in Chinese 20 Apr 82 p 2

[Article by Economic Crop Department, Provincial Bureau of Agriculture: "Sixty-nine Percent of Province's Cotton Sowing Completed Through Diligent Strengthening of Leadership and Firm Attention To Combat Against Drought in Sowing"]

[Text] Since mid-April, from south to north in Hebei Province a new upsurge has begun in cotton sowing. Statistics as of 28 April show 7.55 million mu already planted, and this is 69 percent of the cotton planting quota. Ten counties including Jinxian, Shenze, Wuji, Gaocheng, Chaoxian, Luancheng, Zhengding, and Huolu have already fulfilled their cotton sowing quotas.

Primary reasons for the fast pace and good quality of cotton sowing in the province this year are as follows: 1. Ninety-six percent of cotton producing production teams throughout the province have further consolidated and perfected production responsibility systems, and various cotton-growing policies have also been further implemented. This has further aroused the enthusiasm of the broad masses of cotton-growing peasants who have acted early to combat drought in cottonfields to prepare for sowing, paying strict and careful attention. The area in which soil moisture has been created is large; base fertilizer has been amply applied; and the fine variety area is large. 2. All levels of agricultural scientific and technological personnel have actively signed technical contracts linked to output with communes and brigades, improving technical direction. Throughout the province, training of more than 3.3 million technical personnel has been done in various ways. This includes the training of 3.14 million cotton-growing mainstay cadres, and cotton growing techniques have been brought to every home and household. Each level of agricultural bureau has written several kinds of small booklets on cotton-growing techniques and have published several hundred thousand copies. This has played a very great role in the popularization and improvement of cotton-growing techniques. 3. Strengthening of leadership. All prefectures and counties have convened different kinds of conferences for the purpose of carefully arousing mentalities to prompt and sufficient planting of cotton, and to making concrete preparations. As April dawned, all levels of party and government leaders in cotton-growing areas made the central task in current agricultural production, combat against drought for the sowing of cotton. They concentrated leaders, time, work forces, and tools to combat drought and sow seeds initiating an upsurge to combat drought and sow seeds. Leadership cadres at all levels divided up responsibilities level by level, and 30,000 cadres in government organizations went into the frontline of combat against drought to do planting, to spread experiences, and to solve problems.

Right now places that have not completed sowing are applying an indomitable spirit of combat against drought to wind up sowing. Places that have already completed sowing are rapidly starting a check of soil moisture conditions and of seedling conditions. They have taken effective measures for places missing seedlings, using every possible means to get a full stand of cotton.

HIGH YIELD COTTON GROWING TECHNIQUES OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 9 May 82 p 1

[Article: "How to Effectively Check and Replace Cotton Seedlings, Thin Seedlings and Do Final Singling of Seedlings"]

[Text] Cotton sowing will soon be finished. Next will come the checking and replacing of seedlings, the thinning of seedlings, and the final singling of seedlings. Some thoughts about these techniques are discussed below for the reference of all jurisdictions.

Let us first talk about the checking and replacing of seedlings. The key to checking and replacing seedlings lies in "earliness." The advantages of early replacement of seedlings are: savings of labor, good survival, seedling ease in catching up with the others. Depending on how many seedlings are missed and the time when seedlings are replaced, different replacement methods may be used. One is for cottonfields in which about 40 percent of seedlings are missed requiring forced sprouting and sowing in the empty spaces as replacements. The second is when between 20 and 30 percent of seedlings are missing when the method of replacement is planting with supplemental seedlings. The third is when missing seedlings number fewer than 20 percent and when cottonfield growth has reached the leafing stage. In this case it is necessary to transplant shoots and seedlings, taking seedlings from place in the field where there are too many to fill in bare spots in other places. The essentials of transplanting seedlings are as follows: good weather, small holes, not much water, small seedlings. When transplanting, place the seedling in the hole and then fill in around it with a small amount of soil. Water each hole with 1 or 2 liang. When filling in with soil, do not compact it, and make sure the seedling is in the soil in its former position. This makes for a high survival rate. Fourth is when between 5 and 10 percent of seedlings are missing or when seedlings are still missing after the thinning of seedlings, when transplanting with soil around the roots may be done. At the time of transplanting care should be taken not to disturb the soil on the seedlings and not to damage the roots. Care should begin immediately following replacement planting or transplanting to reduce, insofar as possible, gaps in the overall cotton seedling stand.

Let us talk next about the thinning and final singling of seedlings. Thinning and final singling of seedlings should also be done early rather than late. This is because the quantity of cotton seeds sown is generally several to more than 10 times greater than the density of seedlings that will be actually retained. Numerous seeds mean dense seedlings, and if thinning of seedlings is done late, the seedlings will be squeezed together, making them likely to be spindly. This will cause late squaring and late flowering to the impairment of cotton quantity and quality. Experiments have shown that on irrigated land squaring comes 3 days earlier when plant heights average about 1 centimeter at the time the first true leaves appear as compared with when the third true leaves appear. Consequently after the cotton seedlings have all sprouted and the first true leaf has developed, thinning of seedling and final singling of seedlings must be done to remove the weak ones and leave the strong, to leave the large and remove the small, and to leave the healthy while removing the sickly. Distance between seedlings should be half the distance of plants following final singling. Once the third true leaf has appeared on cotton seedlings, the stem tissue gradually becomes woody and the main root goes down fairly deeply into the soil. Final singling must be done promptly at this time. Density of remaining seedlings should be reasonable so that individual plants will develop well and so it will be possible for plant colonies to bring increased yields. Singling should be done on the basis of soil fertility, amount of fertilization, intensity of care, and output requirements. To realize the full potential for high yields of individual plants, for high yield fields that produce more than 150 gin per mu of ginned cotton that have fertile soil and are well fertilized, density should be aboue 4,000 plants per mu. Cotton fields that produce yields of 100 jin per mu of ginned cotton and are of average fertility should have a plant density of about 4,500 per mu. In sandy, infertile, porous soils where moisture and fertility conditions are poor, most important is the role of plant colonies in increasing yields so density should be above 5,000 plants per mu.

COTTON PLANTING REPORTED UNDERWAY IN DROUGHT CONDITIONS

Shijiazhuang HEBEI RIBAO in Chinese 26 Apr 82 p 1

[Article: "Handan Prefecture Combats Drought To Plant Cotton on Time. Concentrates Forces To Do a Crash Job of Completing Cotton Sowing Tasks"]

[Text] Handan Prefecture has concentrated forces to do a crash job of cotton sowing. As of 21 April, more than 1 million mu had been sown throughout the prefecture.

This year Handan Prefecture has done a solid job of sowing cotton and has a good foundation. Nevertheless numerous disadvantageous factors exist: One is that this year is the 5th year of continuous drought. Cottonfields are entirely devoid of soil moisture; electric power is insufficient; there is a shortage of petroleum fuels, and difficulties in combating drought are great. Second is that the prefecture's cotton growing area has been expanded by more than 800,000 mu over what it had been last year; numerous cotton growing teams have been newly added, and sowing tasks are great. In light of this situation, the Handan Prefecture CCP Committee and government administrative offices enunciated a guiding mentality of "early action, concerted efforts to combat drought, and on-time planting." In order to have sufficient soil moisture for planting on time, it was decided that after 15 April, the emphasis would be shifted from the watering of wheat for greening up of the previous period, irrigation of the soil taking precedence over watering of the wheat. In addition, effective measures were taken to solve the problem of insufficient diesel oil. Close attention was given off-peak use of electricity, greatly hastening the pace of cottonfield watering. After 5 April soil temperatures to a depth of 5 centimeters had stabilized at above 14 degrees, and on 10 April most of the counties in the prefecture began test planting.

COTTON SOWING VIRTUALLY COMPLETED IN SHIJIAZHUANG PREFECTURE

Shijiazhuang HEBEI RIBAO in Chinese 27 Apr 82 p 1

[Article: "Shijiazhuang Prefecture Substantially Complete Cotton Sowing Tasks. Promptly Switches to Checking on Soil Moisture and Seedling Conditions and to Thinning Seedlings"]

[Text] Shijiazhuang Prefecture's Cotton growing quota for this year is 2 million mu. As of 25 April, except for a small amount of dryland cotton where water continues to be carried for the dibbling of seeds, more than 190 million mu have been planted.

More than 95 percent of Shijiazhuang Prefecture's production teams have instituted cotton production responsibility systems linked to output, and this has aroused the enthusiasm of the broad masses of peasants for doing a good job of cotton growing. This year's cotton sowing has four distinguishing characteristics as compared with that of former years. One is that scientific cotton growing techniques have been spread far and wide. Incomplete statistics show the training of a total of more than 850,000 cadres and masses in the prefecture. The special characteristics of the prefecture's major cotton varieties and techniques for sowing seeds to assure full stands have been made known to every household. Second is the large area planted to fine varieties. The area sown to intermediate early maturing fine varieties such as "Jimian No 2" and "86-1" has increased from last year's 780,000 mu to 1,756,000 mu. Third is the wide area for which cotton seeds have been chemically treated. Fourth is the high quality and fast pace of sowing. With the virtual completion of cotton sowing, all areas have turned their attention to care of cotton seedlings. They have launched a general check of soil moisture and seedling conditions, and the thinning of seedlings.

FIGURES GIVEN FOR 1981 STATE GRAIN, OIL PURCHASES

Shijiazhuang HEBEI RIBAO in Chinese 26 Apr 82 p 1

[Article: "Hebei Province Overfulfills 1981 Grain and Edible Oil State Purchase Plans. Varieties in Storage Better Than in Former Years. Procurement of Grain and Oil at Negotiated Prices Scores Startling Success"]

[Text] Hebei Province's 1981 grain and edible oil state procurement plans have been overfulfilled; varieties in storage are better than in former years; and procurement of grain and oil at negotiated prices has scored startling success.

As a result of the steady completion and perfection of production responsibility systems, the enthusiasm for production of the peasants in the province's farflung rural villages was aroused last year, and they triumphed over 3 consecutive years of serious drought to win bumper harvest of grain and oil-bearing crops. Cadres and commune members in the farflung rural villages eagerly surrendered grain to be delivered to the state, and sold surplus grain in active support of the building of the four modernizations. Overfulfillment of grain quotas by 10.8 percent completed state purchase plans for the province as a whole, and 1.1 billion jin more than last year was put into storage. Six counties completeing state grain purchase quotas with more than 100 million jin included Gaocheng, Shulu, Chaoxian, Luancheng, Leting, and Yongnian, 3 more counties than last year. Quantities of soybeans, mung beans, and millet going into storage greatly exceeded those of last year. Purchases of fats and oils exceeded plan by 28.1 percent. While striving to do a good job of grain and oil procurement work, purchase of grain and oil at negotiated prices was begun. A total of 1,065,000,000 jin of grain and 54 million jin of edible oil were purchased at negotiated prices. In addition, grain purchased from outside the province to meet Hebei Province's needs amounted to more than 300 million jin. This played a positive role in replenishing state grain resources, in enlivening city and country markets, and in providing for the livelihood of the people.

IMPORTANCE OF COMPOUND LIVESTOCK AND POULTRY FEED STRESSED

Shijiazhuang HEBEI RIBAO in Chinese 13 May 82 p 2

[Article: "Hebei Province Has Built More Than 90 Livestock Feed Processing Plants. Restructures Feed Composition and Promotes Livestock and Poultry Industry Development"]

[Text] Hebei Province's newly developed livestock feed industry is developing steadily. Statistics from provincial livestock feed units show that 10 prefectures, nine municipalities and 113 counties in the province have set up feed companies, and that more than 90 compound (mixed) feed processing plants have been built with an annual output capacity of 140,000 tons. In addition, five processing plants are under construction in Shijiazhuan, Baoding and Jintai municipalities, and in Luancheng County. From last year until the end of March this year, they have produced and supplied more than 200 million jin of compound (mixed) feeds.

Hebei Province's livestock industry production began in 1978. Growth of the livestock feed industry has played a positive role in changing the composition of the province's livestock and poultry feed, and has promoted development of the livestock industry. Practice has demonstrated that use of compound (mixed) feeds instead of concentrated grain feeds not only lowers livestock and poultry production costs and increases both the commodity rate and commodity quality, but can also save large amounts of grain. The Tangshan Prefecture, Tangshan Municipality, Shijiazhuang Municipality, and Cangzhou Municipality, numerous units have resorted to use of compound (mixed) feeds to replace pig award grain, helping both livestock and poultry growth with a saving in grain and increasing enterprise earnings.

Livestock feed units everywhere in the province have been rather attentive about going down among the masses to investigate and study so that livestock feed formulation science will meet the needs of the masses. Lanfang Prefecture had specialized households make up a formula, which livestock feed units then used to process feed. Livestock feed units in Yuanshi County carried out a survey of the county's chicken raising households and key area households, and formulated feed formulas on the basis of the nutritional needs of chickens in promotion of chicken industry development. In the same county, commune member Zhao Guangting [6392 1683 0080] of Xihantai Brigadeused feed company provided compound (mixed) feed to raise 60 hens, which last year layed

12,045 eggs for a net profit of more than 570 yuan. Not long ago, he provided a briefing on his experiences in using compound (mixed) feeds in raising chickens to a conference of county scientists and technicians, which attracted serious general attention. As the building of the four modernizations develops and people's living standards gradually improve, people demand that the market provide more and better livestock and poultry products, so the livestock and poultry industries will have to grow a great deal. This will require, in turn, that livestock feed production keep apace. Right now many places in the province have not yet directed sufficient serious attention to livestock feed production, and their perception of the importance of compound (mixed) livestock feeds is insufficient. In many newly built livestock feed processing plants the equipment is rudimentary and the degree of mechanization very low. Product quality cannot be assured either. All this should arouse the serious attention of units concerned at all levels, and they should take action to find solutions.

WINDING UP OF COTTON PLANTING REPORTED

Shijiazhuang HEBEI RIBAO in Chinese 14 May 82 p 1

[Article by Economic Crop Department, Provincial Bureau of Agriculture: "Sowing of Cotton in Province Breaks 10 Million Mu Mark. Concerned Efforts to Fight Valiantly Against Drought"]

[Text] Hebei Province's cotton growing areas have triumphed over serious drought. As of 8 May, they had sown 10.16 million mu of cotton, or more than 92 percent of their cotton growing quota. Two prefectures and 44 counties have completed cotton planting plans, and other places are now winding up the job.

This year all levels of leaders have devoted extremely close attention to cotton sowing. Cotton peasant sentiment is at an all time high, and after making full preparations they began sowing in mid-April. Throughout the province 30,000 organizational cadres went down to communes and brigades to give specific guidance. The broad masses of cotton peasants made every minute count in an arduous and valiant struggle to make the most of soil moisture, promptly setting off an upsurge in combat against drought to plant seeds. As a result, the sowing of cotton this year was done 5 to 6 days earlier than last year, and 5 million my of "April seedlings" were assured. Cotton seedlings also sprouted well, more than 80 percent of them sprouting on 82 percent of cottonfields.

Now places that have not completed sowing are giving strict attention to fighting drought by dibbling seeds into the ground to bring sowing to a close in an effort to complete their cotton planting quotas. Places that have already completed their cotton planting quotas are devoting strict attention to timely inspection of soil moisture and seedling conditions, and to filling in gaps and transplanting, using every available means to assure full stands.

HEBEI

INCREASE IN MILLET FARMING URGED

Shijiazhuang HEBEI RIBAO in Chinese 3 May 82 p 3

[Article: "Need to Give Serious Attention to Revival and Development of Millet Production"]

[Text] Millet tolerates drought and infertile soil. It is one of Hebei Province's major grain crops. It is grown over a very wide area. Except for a few flatland areas in the north, it is grown on a certain area everywhere in the province. Removal from millet of the stigma of a "low yield crop," and serious attention to millet production possess important significance.

I. Full Realization of the Importance of Reviving and Developing Millet Production.

1. Rapid restoration and development of millet production is a requirement for national economic development and a demand of the broad masses of people. In 1952, the province's millet growing area amounted to 26.14 million mu or 30.1 percent of the fall grain area. Output totaled 4.18 billion jin, 32.1 percent of total fall grain output. Subsequent to 1958, the millet growing area declined over the years to 8 or 9 million mu, and total output fell to about 1 billion jin, resulting in a very severe shortage of millet in cities and the countryside.

2. A look at Hebei Province's natural laws and economic laws demands revival and development of a certain area of millet. In Hebei Province, 9 out of 10 years are drought years, and during the past several years the drought frequency rate has become increasingly high. The grainfield area in the province assured of irrigation totals only about 30 million mu, which is half the grainfield area. In terms of soil fertility, organic content is also relatively low, less than one percent in most places. But millet is resistant to drought and tolerant of infertility; it is rather widely adaptable, and requires a small quantity of water. It is a surefire crop for infertile, arid areas that resists drought to ward off or rescue from disaster. Millet is rich in nutrients and has high economic value. Millet straw is rather rich in nutrients, aming it a fine fodder for livestock animals and its bran is a fine feed for hogs and poultry. Millet is easy to care for, tolerates storage, can be easily transported, and is suited

to war preparations and preparations against famine. These characteristics of millet imbue it with very great advantages for increased production in the arid areas of the province.

II. Several Major Problems in Current Millet Production

1. Crop patterns are inequitable. As a result of the influence of "leftist" mentality, the growing of a single crop, and regarding millet as a low yield crop the millet growing area shrank unreasonably in 1981, the province's millet growing area amounted to 8.88 million mu, between 3.12 and 6.12 milliln mu less than the area suited to its growing.

2. Few superior varieites of millet and no matching of varieties. Hebei has an abundance of millet varieties, there being no less than several hundred in the province as a whole. But the varieties are numerous, chaotic, and mixed; they are very much unmatched. Purification and rejuvenation of peasant varieties has not kept pace to the impairment of seed purity.

3. Little fertilizer and poor quality. Analysis by units concerned shows that for every 100 jin of grain produced from spring millet, 4.7 jin of nitrogen and 1.6 jin of phosphate has to be absorbed from the soil. At the present time little fertilization of the province's millet fields is done, and even some cases of "sanitary" [unmanured] fields have occurred. Since the sowing season for summer millet is a very short one, fertilizer is particularly inadequate to the impairment of yields.

4. Because sowing is frequently done each year in a slapdash fashion, skipped plants and breaks in furrows occur, and planting density tends to be scant.

5. Continuous cropping year after year, sloppy care, and serious disease and insect pest damage. Currently downy mildew does fairly serious damage to millet, the incidence of the disease being generally from five to 10 percent, or 20 to 30 percent in seriously infected fields. Damage from Chilo infuscatellus is also very severe, the plant pest rate being a general 15 percent, or 40 to 50 percent in seriously affected fields.

III. Problems to be Given Attention in the Revival and Development of Millet Production.

1. Elimination of the lopsided perception of "millet as a low yield crop." Numerous high yeild representative examples attest that in some areas millet can also be a crop that produces consistently high yields. In Hebei Provinces many areas have had yields of 1,000 jin per mu and large area yields of from 400 to 500 jin per mu.

2. Continued readjustment of crop patterns and equitable distribution of varieites. In view of millet's resistance to drought and tolerance of infertility, more millet should be grown in some dry and infertile hill and mountain regions, and dry and infertile plains areas should also grow

more so as to take fullest advantage of millet's increased yields. Places having the water resources can use summer millet as a fine crop for crop rotation. Use of millet as a rotational crop on cottonfields also produces very good results.

3. An effective job of purifying and rejuvenating existing fine varieties, popularization of existing fine varieites, and breeding of new varities. Statistics from provincial seed companies show that the millet varieites grown over a fairly wide area of the province in 1981 were: Qingdaolao, Lugu No 2, Laiwuxian, 7406, Jigu No 1 and Jigu No 2, Tieganhuang, Tieganzao, Henanniao, and Chaoxiangu. These should be extended to cultivation through an adaptation of general methods to specific situations.

4. Increased fertilization and close planting to get full stands, and to promote sturdy seedlings, sturdy plants, and large heads. Nowadays a stand of between 20,000 and 30,000 seedlings per mu of spring millet is rather good, and a stand of 400,000 to 500,000 is good for summer millet. Increases or decreases may be made on the basis of water and fertilizer conditions, and varieties. In fertilizing, organic fertilizer should be the key link and be mixed with a proper amount of chemical fertilizer, attention being given to a combination of nitrogenous and phosphate fertilizers.

5. Effective solution to prevention of disease (downy mildew) in spring millet, to prevention of lodging of summer millet, and to problems with smothering of seeds [218C 4750] in husks during the late stage.

6. For dryland millet the laws governing precipitation should be promptly applied to accumulate and preserve soil moisture. Autumn rains should be used in spring to assure the moisture conditions necessary for sowing. In order to triumph over drought during the emergence of seedlings and drought that sticks in the throat [0595 9126], the periods for sowing, heading, and full ripening should be adjusted in accordance with soil moisture conditions so that heading is done in the rainy season, and the milk ripe stage comes at the right time for drying of grain. Varieties should be selected according to the time they are to be sown, varities requiring a long period of time used for early sowing and varieties requiring a short period of time used for late sowing.

CSO: 4007/431

BRIEFS

WIND, HAILSTORMS CAUSE DAMAGE--A number of areas of Hebei Province have recently been hit by successive wind and hailstorms, and the situation is rather serious in places. The provincial CCP Committee and government have made prompt arrangements for the struggle against natural disasters. They have issued a circular demanding that the disaster areas and the provincial departments concerned take effective action to fight the natural disasters and strive for a bumper harvest. At the same time they have organized four work teams consisting of cadres transferred from the provincial departments concerned. These work teams set out on 23 June for a number of counties and communes in the relatively severely affected prefectures of Xingtai, Shijiazhuang, Handan and Cangzhou, to comfort the masses on behalf of the provincial CCP Committee and government and ascertain the extent of the disaster. They will also help the local leadership to work well, brace their fighting spirits and actively launch the masses to crash-sow, resow where necessary, strengthen tending of the crops, and reduce the damage. They will do everything possible to help the masses to solve difficulties and strive for a good autumn harvest. [Text] [HK010451 Shijiazhuang HEBEI RIBAO in Chinese 24 Jun 82 p 1]

COTTON PLANTING QUOTA OVERFULFILLED--As of 3 May, Henshui Prefecture had planted a total of 1.41 million mu of this year's 1.4 million mu cotton planting quota for overfulfillment of quota. This prefecture's spring cotton planting not only covered a large area, but it was done quickly and well. More than 1.1 million mu of soil in the prefecture had to have moisture added for the sowing of seeds, and more than 4,956,000 cubic meters of crude fertilizer were spread, an average of 2.5 cubic meters per mu. On many cottonfields, chemical fertilizer, cake fertilizer, and phosphate fertilizer amounting to a total of 4,240 tons were spread. How a virtual ful stand of seedlings is growing on 470,000 of the 690,000 mu of cottonfields where seedlings have begun to grow. Cadres and commune members throughout the prefecture are now carefully checking on seedlings and filling in gaps, and loosening the soil to increase warmth in an effort to get full stands of sturdy seedlings in every cottonfield plot. CONFERENCE HELD ON DROUGHTS, FLOOD PREVENTION

SK191010 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 18 Jun 82

[Excerpts] According to our reporter, the work conference convened by the provincial people's government on droughts, flood prevention and waterlogging concluded 18 June. The conference emphatically pointed out: We should implement the principle put forward by the provincial CCP Committee on paying equal attention to drought combating and waterlogging control, conscientiously grasp the work of drought combating, flood prevention and waterlogging control and strive to reap an overall good harvest in agriculture.

The conference pointed out: Since the beginning of May, under the influence of a high pressure system above Baikal Lake, the province has experienced little rainfall, high temperatures and high winds. The rainfall has been 70 to 80 percent less than the corresponding period in a normal year. Temperatures have been 3 to 4 degrees higher. The ravages of the drought have become more serious and are expanding in all directions. As of 12 June, more than 37 million mu of land in 55 municipalities and counties were stricken by drought.

The conference demanded: We should make full use of the existing water conservancy work and give full play to the role of irrigation. We should focus on good crop seedlings and be committed to antidrought work to minimize losses from the drought.

The conference urged localities to accelerate the building of water storage projects in places without water sources. A tendency which warrants our attention is that some counties slacken their efforts to build water storage projects because they had much rainfall last year and soil moisture has been sufficient. Therefore, various localities should pay close attention to this problem and not fall under the influence of changing weather conditions.

The conference made an analysis of this year's flood situation according to the forecast and survey by meteorological and hydrological departments. In July most areas in the province will have 20 to 30 percent more rainfall than the corresponding period in a normal year. But the rains will be uneven, and there will be many torrential rains in some areas. Water volume of the mainstreams of Nenjiang and Songhuajing rivers will increase this year. Water volume of Heilongjiang River [words indistinct]. Relatively serious floods will probably occur on the Raolihe, Mulinghe, Wokenhe and Mudanjiang rivers.

The conference stressed in conclusion: It is an arduous and important task to combat drought, prevent floods and control waterlogging. CCP committees and people's governments at all levels should strengthen leadership over ideological, political and organizational work, establish and perfect a powerful and effective command system, do the work of combating drought, preventing floods and controlling waterlogging and strive to reap an overall bumper harvest in agriculture.

CSO: 4007/459

CONFERENCE HELD ON COMBATING DROUGHT, INSECTS

SK300936 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 29 Jun 82

[Excerpt] The provincial CCP Committee and the provincial government held an emergency telephone conference on 29 June, urging the whole party and all the people throughout the province to immediately go into action and spare no efforts to combat serious drought and insect pests, to resolutely carry on the struggle of combating drought and insect pests to ensure the growth of seedlings through to the end and to win a victory in this struggle. The conference was chaired by Comrade Wang Caoli, deputy governor. Comrade Wang Luming, secretary of the provincial CCP Committee and deputy governor, delivered a speech at the conference.

After elaborating on the achievements in the former stage of the struggle on combating drought and insect pests to ensure the growth of seedlings, the conference pointed out: This year drought and insect pests have occurred in our province with tremendous force and are spreading very rapidly. It is unprecedented in history. There are now 55 counties and cities threatened by drought throughout the province and the situation is worsening. According to the forecast by the meteorological departments, there will not be any heavy rainfalls before 5 July and the drought situation will be worsening. The disasters will be more serious. This year our province will experience a serious grass borer disaster and the situation will be even worse than in 1980 for it will cover a large area, will have a frightful density and will cause serious damage. Grass borers have appeared in our province's 53 counties and cities and 72 agricultural farms, covering 47.69 million mu of farmland. The disaster-stricken areas now reach 19.13 million mu.

Noteworthy is the fact that some cadres and the masses are afraid of difficulty and weary of combat work and have taken a passive and pessimistic attitude. If we fail to solve these problems rapidly and well, it will be impossible for us to win a victory in the struggle of combating drought and insect pests and killing weeds to ensure the growth of seedlings.

The conference urged: We must further mobilize the whole party and all the people to resolutely win a victory in this struggle.

CSO: 4007/459

BRIEFS

PROVINCE COMBATS DROUGHT, PESTS--Some 30,000 cadres and over 2 million commune members in Heilongjiang rural areas are now working on the farmland to combat drought and prevent grass borers. They have irrigated 3 million mu of fields and applied pesticide to 19 million mu of cropfields. This year Heilongjiang Province has dispatched nearly 10,000 motor-driven carts and 15,000 animal-driven carts to transport water and used some 28,000 barrels and operated 23,000 pumping wells to water fieldcrops and seedling beds to solve the water problem of some 100,000 mu of paddyfields. According to initial statistics, the province has utilized 70,000 sprayers and applied 15,000 tons of pesticide to farmland to control grass borers. [SK291057 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 28 Jun 82]

PREFECTURE COMBATS DROUGHT, PESTS--Songhuajiang Prefecture, Heilongjiang Province, has mobilized some 700,000 people to combat drought and insect pests. At present 7.78 million mu of insect afflicted farmlands have been tended. The disaster caused by insect pests in this prefecture has been basically brought under control. This prefecture has operated all pumping wells and made use of all available water resources to water 1.25 million mu of farm crops, easing the threat of drought. [SK01159 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 29 Jun 82]

SOYBEAN APHIDS--In Heilongjiang Province, Acheng, Bin, Wangkui counties and Jiamusi Municipality are suffering from soybean aphid pests. Investigations indicate that 72 to 93 percent of the soybeans are infested with aphids. There are 5 to 19 aphids on each soybean plant. Aphids have also been found in some green peppers, tomatoes, eggplants, and cucumbers in Harbin Municipality. [SK262239 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 25 Jun 82]

BRIEFS

ZHOUKOU PREFECTURE GRAIN PROCUREMENT--Zhengzhou, 26 Jun (XINHUA)--As of 20 June, Henan's Zhoukou Prefecture had procured 410 million jin of marketable grains, hereby overfulfilling procurement plans for summer crops. The prefecture had reaped a bumper wheat harvest from its 7.2 million mu of wheatfields, with the total output reaching 3 billion jin and increasing by 10 percent over that of 1981. [OW021313 Beijing XINHUA Domestic Service in Chinese 0255 GMT 26 Jun 82]

CSO: 4007/459

BRIEFS

HUBEI SUMMER WHEAT HARVEST--Wuhan, 5 Jun (XINHUA)--Hubei Province in central China reports that the output of winter wheat and other grain crops to be harvested this summer are expected to exceed last year's by more than 10 percent, while rapeseed yield is estimated to grow more than 20 percent. Harvesting of rapeseed has just been completed in the province and the wheat crop is being gathered and threshed. The good summer harvest is attributed to the adoption of the job responsibility system by 99 percent of the production teams, careful selection of seeds, increased use of chemical fertilizer and control of plant diseases, according to the provincial agricultural department. Many other provinces in the southern parts of China are gathering good wheat harvests but a number of northern provinces have been threatened by dry spells. SPRING FARMING UNDER DROUGHT CONDITIONS EXPLAINED

Nanjing XINHUA RIBAO in Chinese 4 May 82 p 2

[Article: "Xuzhou Prefecture People Pitch In In the Struggle Against Drought To Win a Bumper Summer Harvest and Assure Full Stands From Spring Sowing"]

[Text] For days on end the broad masses of cadres and people in Xuzhou Prefecture have urgently mobilized to pitch in to struggle against drought to assure harvests of wheat, barley and naked barley, and to assure full stands of spring sown crops.

This year the volume of rainfull in Xuzhou Prefecture has been more than one-third less than during the same period in most years. This plus the rise in temperatures during recent days has meant an increasingly serious drought situation. More than 2 million mu of wheat, barley, and naked barley in the prefecture have been seriously drought-striken, and spring sown crops such as cotton and corn have also been seriously threatened. Faced with drought, leaders of all levels in Xuzhou Prefecture have taken vigorous action. They have led the broad masses of cadres and people to pitch in to struggle against drought. Feng County transferred more than 170 organization cadres under the leadership of officers in charge at the county CCP Committee and county government to help fight drought in 7 communes where the drought situation is particularly serious. Throughout the county all commune cadres have assumed individual responsibility for tracts, brigade cadres have assumed responsibility for production teams, and production team cadres have assumed responsibility for machines, for pump wells, and for field plots. Daily more than 7,000 pump wells ahd more than 2,800 water pumps in the county join in the fight against drought. In order to tap water sources fully and expand the irrigated area, they have aroused commune members to use more than 4,400 hand pumped wells that use neither petroleum fuel nor electric power. Right now in Pei County, 280 electro-mechanical irrigation stations, more than 5,000 wells, and 100,000 horsepower have all been put to use to combat drought. In Tongshan County the broad masses of cadres and people have overcome a psychology of waiting for rain to fall, daily sneding out more than 100,000 people to water the wheat and do rush planting. Faced with a shortage of surface water, while raising water and diverting water, Ganyu County has adapted general methods to local situations for large-scale digging so that river water and pond water will flow downward from one level to another, doing everything possible to increase sources of irrigation water. In the hilly region of this county, 10 communes have already dug ditches so that pond water will flow from one level to the next at more than 600 places. They have intercepted stream flow at more than 200 places. Now the county is watering 400,000 mu of wheat, barley, and naked barley. As of 28 April, the prefecture was combating drought to irrigate more than 1.5 million mu of wheat, barley, and naked barley, to sow more than 940,000 mu of cotton, 300,000 mu of spring corn, and more than 300,000 mu of peanuts.

PROVINCIAL COTTON GROWING AREAS COMPLETE PLANTING

Nanjing XINHUA RIBAO in Chinese 9 May 82 p 1

[Article: "Province Completes Direct Cotton Sowing Quota on Time"]

[Text] The broad masses of cotton-growing peasants in cotton growing areas throughout the province have adhered to cotton growing plans. While giving attention to the propagation of cotton seedlings for transplanting, they have also completed on time their direct cotton planting quotas. Cotton has been directly planted across an area of 5.94 million mu.

This year, as a result of the perfection and consolidation of cotton production responsibility systems, enthusiasm among cotton peasants for the growing of cotton is high. The pace of cotton planting has been rapid, quality good, the sowing season concentrated, land preparation done painstakingly, and base fertilization fairly adequate. In most parts of Nantong Prefecture, green manure was buried to serve as base fertilizer in directly planted cottonfields, and nightsoil and phosphate fertilizer was also added to some. In Yancheng Prefecture, winter plowing and spring cultivation of cottonfields has been done well, and for most fields chemical fertilizer has been used as the base fertilizer. The cotton-growing peasants have sown their seeds in patterns. In many places they have used string to mark rows; seeds have been planted evenly and there has been no cracking of soil around plants.

Early sown cotton has already reached a full stand, and some shoots are now pushing through the soil. Everywhere seedling stage care is being given and the "five rush" jobs in advance of the wheat harvest are being done.

NEW EMPHASIS GIVEN ORGANIC FERTILIZER PRODUCTION

Conference Held

Nanjing XINHUA RIBAO in Chinese 7 May 82 p 1

[Text] Adherence to organic fertilizer as the key link, and taking the road of agricultural development that fits in with the situation in Jiangsu Province were the main topics of discussion at the provincial fertilizer work conference recently convened by the provincial government in Lianshui County. The conference required all leadership comrades on the agricultural front to make clear this guiding mentality and to treat organic fertilizer production as a strategic task to produce genuine results.

Comrade Zhou Ze [0719 3419] made a speech at the meeting.

Prefecture (or municipal) and county officers in charge who attended the conference made on-site inspections of fertilizer production in some communes and brigades in Lianshui County. They listened to briefings on the experiences of representative units; they linked realities of individual places in conscientious discussion; and they put forward some ideas about building up organic fertilizer.

The conference affirmed the achievements and experiences of Jiangsu Province in building up organic fertilizer, and it analyzed some of the problems manifest in some places in recent years from neglect of organic fertilizer production. Everyone evinced marked interest in the successful experience of Lianshui County in having proceeded from local realities to undertake water conservancy, the growing of green manure, and improving paddy rice. After more than 10 years of unflagging efforts, Lianshui County, which has always had many disasters and low yields, have brought about the irrigation of most of its farmland and has produced a forest network, while at the same time growing green manure on a large scale. It has transformed drylands to wetlands and has effectively changed infertile saline-alkaline soils. The soil has become more fertile the more it is farmed; yields have become increasingly high; and grain output has increased for 7 consecutive years. In the 4 year period between 1978 and 1981, output increased by 279 million jin, a rate of incremental increase averaging 10.8 percent. This was achieved, moreover, with fairly low energy consumption for high benefits and fine economic results. At each site everybody saw not only large areas of vigorously growing winter green manure, but also row upon row of mud and grass composting ponds filled with fertilizer. They also saw methane pits in current use. Comrades at Yancheng Prefecture conducted briefings on their experiences in the adaptation of general methods to local situations in setting up an equitable crop rotation system for a combination of nurture and use to build up soil fertility in order to win increased grain and cotton yields. These briefings also provided everyone with much inspiration. As a result of soil surveys, Wu County revealed existing problems with soil fertility and found the reason why agricultural production fluctuated without moving forward.

Through their discussions, delegates derived the following consensus: Production of organic fertilizer bears on soil improvement, build-up of soil fertility and maintenance of consistently high yields. It bears on the internal economic structure of agriculture, on equitable crop distribution patterns and the farming system, on the agricultural ecological balance, and on economic benefits derived from agriculture. It is a major matter of significance for the situation as a whole, and this significance cannot be underestimated. Many comrades said that it is necessary to understand anew the importance of organic fertilizer production and consciously to put into effect a program of "three paramounts" in soil and fertilizer work, persevering in taking the road of the paramount of organic fertilizer in development of agriculture.

The conference drew on collective wisdom and absorbed all useful ideas. It studied how to imcorporate the build up organic fertilizer, proposing diverse channels for increasing fertilizer sources such as large-scale growing of green manure, developing a livestock industry, increasing barnyard manure, raising the "three water plants," growing duckweed, establishing duckweed fertilizer, storage, composting grass and mud in ponds, piling compost at high temperatures, promoting use of methane gas fertilizer; and production of micro-organism fertilizer, etc. All successful past experiences should be summarized and promoted. But one of the most fundamental things is correcting the guiding mentality of leaders at all levels to place this work in its proper position, to formulate rules and diligently carry them out, to establish and perfect fertilizer production systems of responsibility, make overall arrangements on crop patterns, and study and solve pertinent policy problems. The conference hoped that units concerned would further establish thinking in which agriculture is the foundation, strengthen cooperation, and promptly solve problems in the production of organic fertilizer.

The conference called upon cadres and masses throughout the province to rally their spirit, take advantage of present favorable opportunities, and go in for organic fertilizer production in a big way, and at the same time take a firm grip on all links in agricultural production, exert great efforts to win an all-around bumper harvest in agriculture this year, and also create conditions for continued development of agricultural production.

Role of Organic Fertilizer

Nanjing XINHUA RIBAO in Chinese 7 May 82 p 1

[Editorial: "Insist on Taking Organic Fertilizer as the Key in the Development of Agriculture"]

[Text] Fertilizer is food for farm crops. Increased fertilization with organic fertilizer to nurture soil fertility is a major way in which to develop agricultural production. Several years ago, the provincial CCP Committee proposed a program of "three key links" in soil fertilizer work. This was a combination of organic and inorganic fertilizer with organic fertilizer being the key link; a combination of barnyard manure and commercial fertilizer with barnyard manure being the key link; and a combination of soil nurture and soil use with soil nurture being the key link. The central idea was the key link of organic fertilizer. The situations reported by all jurisdictions attending the provincial fertilizer work conference have shown that all places that have adhered to the implementation of this program have been able to achieve more soil fertility, the more farming done, fairly consistent and high yields, and fairly low farm costs. In those places that have ignored or acted contrary to this program, the situation has evolved in just the opposite direction. Practice has shown this program to be consistent with agricultural production's objective laws, and to be correct. In the future, we must unswervingly continue to carry out a program in which organic fertilizer is the key link so that the province's agriculture will take the path of small consumption of energy, good ecological environment, high economic gains, and both consistent and high yields.

Use of organic fertilizer to nurture soil fertility is a fine tradition in the province's agriculture. After liberation, and particularly during the late 1960's, organic fertilizer saw fairly large growth, and the masses accumulated abundant experience through practice in the building of soil fertility. Take green manure as an example. The area planted to it increased and the regions in which it was grown expanded. It played a major role in improving low yield soils, in "changing drylands to wetlands," in "changing waterlogged fields to drylands" and in promotion of the "three crop system." After many years of effort, a rational crop rotation system suited to circumstances in various places gradually developed; results of the development of farmland water conservancy construction were consolidated, soil fertility was increased; and development of agricultural production as a whole was advanced.

However, since the mid-1970's, with the steady increase in chemical fertilizer, the importance of organic fertilizer gradually came to be overlooked by some people. Some places either consciously or unconsciously lost the fine tradition of the key link of organic fertilizer. The green manure area greatly declined and a striking decrease occurred in the use of organic fertilizer. This brought about a proportional imbalance between organic and inorganic fertilizer. In some places stiffening of the soil, deterioration of fertility, and a decline in cultivability of the soil occurred. Were this state of affairs to continue unabated, very possibly agricultural production might fall into the predicament of high energy consumption, high costs, low efficiency, and low returns, and this would arouse a high degree of serious attention all along the frontline of agriculture. Our emphasis today on the key link of organic fertilizer derives from the correct conclusion reached after having summarized both positive and negative experiences.

To say that farming is inseparable from organic fertilizer is a principle that everyone understands. China's agricultural production has gone on for several thousand years without let up, demonstrating that our ancestors understood nurturing and preserving soil fertility. Then, why have some comrades forgotten this tradition and neglected organic fertilizer production? This is because their perception of the importance of organic fertilizer has halted in the perceptual stage; they have no high degree of rational perception of its strategic significance. Chemical fertilizer is very important but one must have a definite proportion of organic fertilizer to serve as a base fertilizer; only then can chemical fertilizer be fully effective. If one fertilizes solely with chemical fertilizer with no admixture of organic fertilizer, he taps the soil's reserves and such a situation cannot long endure. Agriculture is a century-spanning enterprise. To dig up the wealth that our ancestors have layed down, and to plunder our descendents' ricebowls positively will not do.

Scientific agricultural experiments and practice everywhere have also further demonstrated that continued taking of organic fertilizer as the key link helps steadily increase soil fertility levels, helps consistently high yields in agricultural production, helps increase benefits from chemical fertilizer in increasing yields, and also helps increase economic benefits from agriculture. Adherence to the paramount of organic fertilizer is positively not an expedient measure, but is rather a program for vigorous development of agriculture to create wealth for posterity, requiring perseverance over a long period of time.

Adherence to taking organic fertilizer as the key link requires implementation of the various programs and policies that have followed from the 3d Plenary Session [of the 11th Party Central Committee], building and perfecting fertilizer production responsibility systems, and making it a major ingredient in the perfection and stabilization of agricultural production responsibility systems.

Adherence to taking organic fertilizer as the key link requires linking it to the readjustment of agriculture and to grain, cotton, and oil bearing crop production as well, with the formulation of regulations about building organic fertilizer, arranging crop patterns in an overall way while taking all factors into account, and while assuring no further reduction in the grain growing area, to adapt general methods to specific situations to establish equitable crop rotation systems so as to achieve a combination of soil use and soil nurture.

Adherence to taking organic fertilizer requires consideration of local resources to develop diverse channels for the production of organic fertilizer. Farming, raising [of livestock or aquatic products], gathering, or manufacturing all have a special place in the production of organic fertilizer. It is necessary energetically to develop herbivorous animals to advocate green storage of fresh hay, to return digested materials to the fields, and take the path of farming and livestock raising in combination. Growing of the "three aquatic plants," propagating duckweed, composting grass and mud in ponds, high temperature composting, promotion of methane pits, and return to the fields of stalks and stems should continue to be advocated, and fresh experiences created as well.

Adherence to taking organic fertilizer as the key link also requires that in the movement for scientific farming, popularization of and indoctrination in a scientific understanding of foil fertility must be thoroughly done. Soil surveys should be undertaken conscientiously, serious attention given to demonstrations, and application of soil survey results promoted. In addition, scientific study and technical promotion work on soil fertility should be strengthened, traditional agriculture and modern science and technology combined.

Adherence to organic fertilizer as the key link requires the carrying forward of a spirit of self-reliance and arduous struggle. Organic fertilizer production requires great efforts. Unwillingness to work hard and sweat, thoughts of avoiding work, and fear of hardships will mean that this endeavor cannot be carried out successfully.

Adherence to organic fertilizer as the key link positively is not to say that chemical fertilizer production can be slackened. Right now some chemical fertilizer plants do not operate at capacity. All levels of planning units and materials allocation units should equitably distribute energy to assure normal production of chemical fertilizer. At the same time it is necessary to apply scientifically and rationally chemical fertilizer to increase the chemical fertilizer utilization rate. A great potential lies in this.

The crux of adherence to organic fertilizer as the key link lies in the leadership straightening out the guiding mentality and truly putting it on their daily agendas, solidly studying it, and implementing measures. They should use representative cases as examples, investigate and study, and solve real problems. Now is a golden time to do a lot about organic fertilizer. We must take a long-range view and take firm hold of the present, rapidly organize action, and start an upsurge of mass enthusiasm for acting on organic fertilizer to win an all-around bumper harvest in agriculture this year, and to create a new situation for flourishing development of the province's agriculture.

COURAGEOUS STRUGGLE AGAINST DROUGHT URGED

SK160437 Changchun Jilin Provincial Service in Mandarin 1100 GMT 15 Jun 82

[Station commentary: "We Must Not Be Disheartened in Face of Drought"]

[Excerpt] Some counties, communes and brigades in our province are suffering from an extremely serious drought, which is growing worse and worse. There are two prevailing attitudes toward the natural diaster. One is not to lose heart in face of the serious disaster and to brave the elements to strive for a good harvest. The other attitude, which is common in a minority of cadres and masses, is to become pessimistic and to feel disheartened. They even (?abandon the plow) and are trying to look for new means of livelihood. So far this has not become the main trend of the situation, but it nonetheless warrants our complete attention. At present, antidrought work is still in a critical stage. Instead of wavering we must evince increased confidence, concentrate all available strength to combat the disaster and exert utmost efforts to minimize a reduction of grain output. We must educate the cadres and peasants to overcome the natural disaster by relying on the party and the collective.

Previously, party committees and government at all levels organized materials, labor power and vehicles to give disinterested assistance to communes and brigades in the disaster areas. Bringing into play the strength of the collective economy, the communes and brigades have executed replanting without a hitch. It is dishonorable to walk out on the collective in face of disaster. Moreover, it is inadvisable. History has shown that it is impossible for a single household to withstand the elements. In this sense, it is true that a disaster is dreadful. But what is more dreadful is losing one's heart in overcoming the disaster and the centrifugal tendency of abandoning the collective. Every party member and cadre must increase his confidence and lead the masses to successfully overcome the disaster and provide disaster relief.

EFFORTS TO PLANT CROPS DESPITE DROUGHT SKETCHED

Shenyang LIAONING RIBAO in Chinese 28 Apr 82 p 1

[Article: "Provincewide Upsurge in Fight Against Drought For Planting. 11.55 Million Mu or One-Third the Area to be Planted Already Sown"]

[Text] Spring farming and sowing in Liaoning Province has experienced an upsurge in the midst of a struggle against serious spring drought. Statistics as of 23 April show an 11.55 million mu area, or one-third the area to be planted, already sown. This includes Tieling Prefecture, where soil moisture conditions are fairly good, and Shenyang Municipality in both of which the pace of sowing has been rather fast. In the cities of Liaoyang, Anshan, Fushun, and Yingkou, plnating has been done either more rapidly than or equally rapidly as during the same period last year. In some communes and brigades, the planting of cereal grain crops has already been completed, and planting of cotton and peanuts has begun.

Ever since last winter, an overwhelming majority of prefectures throughout the province have had virtually no snow, and though a little rain has fallen several times since March of this year, the quantity of rainfall has been very small and its distribution very uneven. Now the drought situation is spreading very rapidly and the drought area gradually expanding. During March and April, except for Dandong Municipality, the drought area has extended to the eleven remaining municipalities and prefectures in the province. As of 23 April the area seriously striken with drought covered an area of 17 million mu. In Chaoyang Prefecture for the more than 30 months from the fall of 1979 until 23 April this year no soaking rain has fallen. The spring drought in Dalian Prefecture has been the worst in the 77 years since meterological data has been recorded. Everywhere the broad masses of rural cadres and commune member masses have struggled against the spring drought. Whenever it has been possible to rush plant while soil moisture has been sufficient to support growth, they have rush planted, and whenever it has been possible to fight drought to plant, they have fought drought to plant. Another mu planted is another mu. In Chaoyang Prefecture where the drought situation is serious, 841 prefecture and county organization cadres were formed into a work team to fight drought. Led by comrades in charge at the Prefecture CCP Committee and government administrative offices, they went into the frontline of production, sorted out matters and gave tailored guidance. The zeal of the broad masses of commune members to fight drought is high. In the three municipalities and prefectures of Chaoyang, Jinzhou and Dalin, almost 1.3 million workers, more than 1,000 motor vehicles, 4,000 tractors, and more than 22,000 animal-drawn carts daily join the fight against drought to plant. Garrison forces in Jin County have also sent out 700 officers and men to join in the fight against drought to plant.

Right now the dominant problem in spring planting and production is the extremely uneven pace of planting everywhere as a result of the drought. In some places the pace of planting is slow, and they have planted only 20 or even only 10 plus percent of what they had planted during the same period last year. Because of the decline in soil moisture content as a result of the enduring drought, plus the high temperatures and strong spring winds, unless the mentality of waiting for the heavens to rain is overcome and rush planting to take advantage of what soil moisture is available emphasized in combat against drought to plant, there is danger that the farming season will be missed.

DEEPER UNDERSTANDING OF RESPONSIBILITY SYSTEMS URGED

SK240321 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 Jun 82

[Excerpt] The Hulun Buir League CCP Committee recently issued a decision, urging cadres at all levels throughout the league to continuously enhance the people's understanding of implementing all kinds of production responsibility systems and, through practice, correctly handle the relations between unified planning and fixing responsibility by contract in an effort to consolidate and improve the production responsibility systems. After universally implementing various forms of production responsibility systems, a gratifying situation in which the grain output has increased and the commune members have received more income has appeared in the rural areas of Hulun Buir League. However, due to the restraint of the leftist phenomenon in the past, many people have failed to completely understand why we should implement various forms of production responsibility systems in rural areas. Some grassroots cadres have maintained that the implementation of the two responsibility contract systems is just an expedient measure to enable the people to dress warmly and to eat their fill. They have failed to exert all their strength to implement the two responsibility contract systems to serve the wishes of the people. In view of this, the Hulun Buir League CCP Committee recently held an enlarged standing committee meeting and, by adopting the method of analyzing typical cases, organized the banner and municipal principal leaders of the rural areas attending the meeting and all participants concerned to jointly examine, listen to and discuss the exemplary cases of the league's 14 units which have implemented all forms of production responsibility systems, to sum up their experiences to find out people's ideological gaps and to unify their thinking. All participants held that regardless of what forms of production responsibility systems are implemented in rural areas, the nature of the basic means of public ownership systems of production, including the land ownership system will not be changed for a long time and that all responsibility systems must be continuously improved through practice.

CSO: 4007/459

BRIEFS

WEATHER FORECAST--Affected by a cold spell moving toward Nei Monggol from the Mongolian People's Republic, the central and eastern parts of Nei Monggol region will have thundershowers 20-23 June. The temperature will drop suddenly. This will adversely affect livestock production. The regional meteorological observatory urged all localities to make preparations for this. [SK201036 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 19 Jun 82]

LIVESTOCK BREEDING--Livestock breeding in Nei Monggol region develops rapidly thanks to the responsibility system and good climate. At present, some 10,174,000 head of young animals have been born, an increase of 932,000 head over that of the corresponding 1981 period. Some 1,119,000 more head of young animals survived than in last year. [SK271056 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 Jun 82]

REGIONAL WHEAT--The 4.8 million mu of wheat in Ulanqab League in Nei Monggol region is growing very well. As of 10 June, about 450,000 labor forces had joined in field management, 4.8 million mu of farmland had been plowed, 53,000 mu had been fertilized and 127,000 mu had been irrigated. [SK181100 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 17 Jun 82]

NEI MONGGOL LIVESTOCK RAISING--Hohhot, 21 Jun (XINHUA)--Nei Monggol autonomous region has since last July increased its livestock by 9.5 million head, a rise of 2.7 percent or 1.11 million head more than in 1981, according to figures by the region's animal husbandry department. The figures indicate that the livestock survival rate was 93.4 percent. Compared with 1981, 300,000 more head of livestock survived and the miscarriage rate dropped 50 percent. In addition, 300,000 head of improved strain and breeds were added. Last year, the department said, the region harvested 3,315 million tons of fodder, on top of 250,000 tons of silage and 30,000 tons of concentrated fodder and built 2.73 million livestock sheds and paddocks, together ensuring that the animals would survive the hard winter. STEADY INCREASE IN RICE YIELDS REPORTED

Yinchuan NINGXIA RIBAO in Chinese 12 Apr 8] p 2

[Article: "Yinchuan Prefecture's High Rice Yields Last Year Awarded Science and Technology Promotion Award. The More Scientific Farming the Greater the Benefits. Paddy Rice Yields Per Unit of Area Continue To Climb"]

[Text] Rice yields last year from the 710,000-mu Huang He diversion irrigation area in Yinchuan Prefecture averaged 975 jin per mu (customary mu), and in 5 of the 9 counties (or suburbs) where the growing of rice is concentrated, yields averaged more than 1,000 jin per mu. Rice yields from an area that amounts to only 6 percent of the total area sown to grain in the prefecture accounted for 29 percent of the prefecture's total grain output. This new agricultural development was awarded the State Agricultural Commission and the State Science Commission's agricultural science and technology promotion award.

In the immediate post-Liberation period, rice yields from the prefecture's Huanj He diversion irrigation area averaged only somewhat more than 280 jin per mu, and were as low as 178 jin. During 8 of the past 9 years, however, except during 1976 when outputs were reduced as a result of serious natural disasters, rice output has steadily risen. This fully demonstrates the importance of scientific farming.

Formerly the Huang He Diversion irrigation area had always scattered "rice in waves," but in 1958 research units experimented with the transplanting of rice seedlings, and during the subsequent 9 years they accumulated experiences with success and failure through practice. By 1966, the transplanted rice seedling area amounted to 150,000 mu. After 1970, a new technique of rolled seedlings (transplanting of small seedlings with soil attached) was promoted to solve the contradiction between the slow development of seedlings propagated in water and the shortness of the season for transplanting seedlins. The transplanted area rapidly expanded, and by 1979 transplanting of rice came to be done virtually everywhere. During the past several years some places have practiced the digging of seeds. Resultant yields have been no less than from the transplanting of seedlings, and economic benefits are rather good.

During the early 1950's, mostly local white husk large paddy was planted, but it was susceptible to rice blast and outputs were both low and inconsistent.

Ever since 1956 all areas have promoted fine varieties such as Jingzu 107, Qingsen No 5, Guoguang, and Gongwen No 12 and No 10. Beginning in the 1970's long growing, disease resistant, high yield fine varieties Jingyin No 39, Aifeng No 2, Tianjin Zaofeng began to be introduced, and Ninggeng No's 3 and 4 were bred. With each replacement and promotion of a variety, rice outputs rose substantially. Now virtually nothing but fine varieties of rice are grown.

In the Huang He diversion irrigation area, saline-alkaline soil and wet low-lying soil exists over a fairly wide area, to the serious detriment of increases in rice output. For many years all jurisdictions have energetically dug drainage ditches to lower the water table, have grown green manure, and have gradually come to fertilize with a mixture of nitrogenous and phosphate fertilizer in a sensible way for steady improvement in the soil and gradual increase in its fertility.

Scientists and technicians and the broad masses of commune members in rice growing areas have also devoted much effort to intensive farming and to the eradication of diseases and weeds. Rice blast, Bakanae disease, and bacterial blight are the three major diseases in the prefecture's rice growing areas, and they have now been substantially brought under control. Barnyard grass, sanlingcao [0005 2789 5430], and yanzicai [4190 1311 5475] are the three major weed pests in the rice producing areas of the prefecture. Striking results in their eradication have been achieved with herbicides, use of which is being steadily expanded and promoted. Now, farm scientists and technicians and the broad masses of cadres and commune members are in process of conscientiously summarizing experiences in bumper rice yields in order to further develop rice production in an effort to provide both city and country people with more and better rice.

INCREASED FISH PRODUCTION URGED

Yinchuan NINGXIA RIBAO in Chinese 26 Apr 82 p 1

[Article by Commentator: "Genuinely Strengthen Leadership to Give Attention to Fishing Industry Production"]

[Text] During recent years, output of fish varieties has increased year after year in Yinchuan Prefecture to bring an end to the situation of fluctuation and decline. Nevertheless average per capita fish output in the prefecture as a whole remains very low, and the problem of getting enough fish to eat is still a conspicuous one. For this reason, the hastening of fishing industry development and reestablishment of the prefecture as a land of fish and rice remains an urgent requirement for the broad masses of people in the prefectur's cities and countryside.

The key to increase in fishing industry output lies in improved understanding and strengthened leadership. We must fully recognize the major importance of accelerated development of the prefecture's fishing industry production for fullest development for use of the prefecture's natural resources, for making the prefecture's rural economy prosper, for enlivening markets, and for improving the livelihood of urban and country people in the prefecture. For this reason, all levels of leadership, particularly county CCP committees and county governments should devote serious attention to fishing industry production in the same way as they devote serious attention to grain production, and place fishing industry work on their important daily agenda, devoting attention to it several times each year. A single leadership cadre should be made primarily responsible for managing this work, and he should go down into the frontline of fishing industry production to investigate and study, and to give prompt help for solution of genuine problems. Comrades in aquatic products and water conservancy units should arouse their spirits, overcome hardship and work hard, becoming active staff officers for CCP committees and governments for the organization of fish raising tasks.

Mass enthusiasm for the raising of fish is currently very high. All levels of leaders and units in charge must do a good job in every respect so that mass enthusiasm for the raising of fish will be brought into full play. One, they should solve problems about water surface use rights. They should first divide up the water surfaces on the basis of ownership, those owning them being responsible for working them. Water surfaces belonging to communes and brigades, should be worked by the collective, and scattered water surfaces not readily workable by the collective may be assigned to commune member household for working. However, individuals may not rent them or sell them to others. Water surfaces in dispute should have their ownership promptly and equitably decided so that fishing industry production will not be imparied. Two is good organization of fry supply. Each county is to gradually establish fish breeding farms. Existing state fishery farms should diligently tap potential, doing everything possible to breed more fry, and collective fishery farms having the conditions should also be organized to breed fish fry to satisfy, insofar as possible, the large scale requirements for fish fry of individuals and of fishing units. Third is to supply technical guidance in the raising of fish to fish raising units and individuals who lack knowledge of such techniques by running training classes and by making the rounds to give instruction. Fourth, is reorganization in coordination with public security units of fishing industry production order, dealing severely with those who seriously damage fishing industry production. Fifth is help to state owned and collective fish raising units in the establishment and perfection of various forms of production responsibility systems for continued solution to the problem of "eating out of a large common pot."

PREFECTURE ISSUES EMERGENCY DROUGHT NOTICE

Jinan DAZHONG RIBAO in Chinese 3 May 82 p 1

[Article: Yantai Prefecture Takes Emergency Action to Fight Drought and Assure Spring Planting. Drought Situation Continues to Develop. Spring Sowing Reaches Critical Time"]

[Text] The drought situation in Yantai Prefecture continues and the fight against drought for spring planting has reached an extremely urgent and critical time. In order to insure that spring planting is done on time, the Prefecture CCP Committee and government administrative offices have issued an emergency notice requiring that the entire party take action and that all the people mobilize to fight drought and assure spring sowing. The notice provided for four measures:

1. From the Standing Committee and deputy commissioners of the Prefecture CCP Committee to principal leaders in the CCP and government of all counties and municipalities and comrades in positions of responsibility in all prefecture and county departments, a clear division of labor is to be made and responsibilities clearly assigned for rapidly leading the broad masses of cadres into the frontlines of the fight against drought, sparing no effort in endeavors to fight drought and do spring planting.

2. Immediate organization throughout the prefecture of all vehicles that can move (10,000 motor vehicles) for the hauling of water to fight drought. Vehicles under the jurisdiction of the prefecture and those belonging to Yantai municipal enterprenurial enterprise units are to be organized centrally by the Prefecture CCP Committee and government administrative offices. County and municipal vehicles are to be the responsibility of county and municipal CCP committees for organization. Vehicles belonging to garrison forces and central government, provincial, or prefectural entreprenural units may be locally requested for use. Locations, units, tasks and times should be set for all vehicles engaged in the fight against drought, and specialists are to go to sites to take command. In rural villages all tractors are to be used for hauling water and none may be used for commercial hauling.

3. Every available means is to be used to tap potential and to use petroleum where it will do the most good. Within distribution quotas established by the state, all petroleum in storage should be used unstintingly during the present circumstances to fight drought. When there is petroleum in storage that is not put to use to the impairment of the fight against drought or delay in spring planting, those responsible will be investigated and responsibility fixed. At the same time it is necessary to give attention to conservation of petroleum.

4. Increase in spring sowing measures to assure quality of spring sowing. One mu planted is 1 mu planted, and 1 mu planted is 1 mu that produces. There can be positively no sowing of seeds on parched land. In places where the drought situation is particularly severe, a good job of growing corn seedlings should be done and preparations made to transplant them. All counties, communes and production brigades are to make unified plans pertaining to water resources, with centralized allocation for use.

The Yantai Prefecture CCP Committee and government administrative offices have required leadership comrades at all levels of CCP Committees and government throughout the prefecture to give close attention to development of the drought situation, to have a full understanding of progress in fighting drought to do planting, to intensify direction and control, to learn about new circumstances on time, and to solve problems that appear.

FISH BREEDING IN RESERVOIRS CONTINUES TO DEVELOP

Chengdu SICHUAN RIBAO in Chinese 13 Apr 82 p 1

[Article by SICHUAN RIBAO correspondent: "Fish Breeding in Reservoirs Continues To Develop in Our Province--Fish Output Increased to 13,580,000 Jin or 27.6 Percent Over the Previous Year"]

[Text] Fish breeding in reservoirs continues to develop in our province. Last year, the total fish output reached 13,580,000 jin, a net increase of 294,000 jin or a 27.6 percent increase over the previous year. The average per-mu output was increased by 2.95 jin; the average output value per worker and staff member increased by more than 240 yuan; and the water surface utilization rate reached 83 percent.

Fish breeding in reservoirs is an important feature in the comprehensive use of reservoirs and the development of economic diversification. Since last year, the water conservation departments have conscientiously carried out the policy of giving benefits to those who have invested in the repair and upkeep of reservoirs. They also recognized the rights of ownership and administration by these investors, firmly supported the system of unified control over both water and fish by establishing organs at various levels, and provided more active leadership over fish breeding. The introduction of the system of responsibility for production in various forms suitable to the local conditions has greatly aroused the enthusiasm of workers and staff members in fish breeding.

The water conservation administration departments at various levels also organized the fishery personnel to learn from the advanced units, invited specialists and technicians to give on-the-spot lectures, and held short technical training courses for the reservoirs' technical personnel in order to improve their technical skill in feeding and fishing. Thus on the basis of a sustained increase of output in the past 2 years, new achievements have been made in fishery in the reservoirs in the province, and a number of typical high-yield units have emerged.

At present, the reservoir administration units in various localities are stepping up their work in fry breeding as a preparation for the spring flood. They hope to produce more large fish and to maintain a high yield for this year so that there will be a larger supply of fresh fish for the urban and rural population.

TIANJIN

CONSTRUCTION OF LEAK-RESISTANT DITCHES REPORTED

Tianjin TIANJIN RIBAO in Chinese 29 Apr 82 p 1

[Article by Wang Hengzhi [3769 1854 2535]: "Reduction in Water Seepage for Expansion of Irrigated Area. Municipality's Rural Villages Have Repaired More Than 1,100 Kilometers of Ditches To Prevent Leaks"]

[Text] During the past several years, Tianjin's rural villages have repaired more than 1,100 kilometers of various kinds of ditches to prevent leakage. These ditches control an irrigation area of more than 220,000 mu, and their repair has played a major role in the struggle to conserve water in the fight against drought.

As a result of 3 consecutive years of serious drought, the municipality's water resources have become increasingly short. In order to make limited water resources do the most good, ever since 1980 the state has provided subsidies to help communes and brigades build leak-resistant ditches. Some communes and brigades in quite a few suburbs and counties, including Wuqing, the northern and western suburbs, and Tanggu, have carried forward a spirit of self-reliance in an active pooling of funds, the transportation of materials, and the organization of construction to bring about fairly rapid development of projects to prevent leaks in the municipality's farmland irrigation ditches. As of now, prevention of leaks in ditches has been extended to a fairly large number of communes and brigades in the municipality's 12 suburban areas. Statistics show that during last year alone the municipality built more than 360 kilometers of leak-resistant ditches. Most of these leak-resistant ditches have been connected to pump wells, and some have been linked to pump well and small irrigation pumping stations. In the use of both well water and river water for irrigation, water conservation benefits may be attained. Most of the irrigation ditches have been constructed of bricks or stone lined with concrete. Some communes and brigades got locally available materials such as stones, bricks, and pipes to build ditches, obtaining rather good results in making them leak-resistant.

Construction and promotion of leak-resistant ditches has been remarkably effective in conserving water to fight drought in the municipality's rural villages. First it has reduced loss of water in transit through ditches and enlarged the area that can be irrigated. Loss of water from the concrete leak-resistant ditches built by Huiguokou Brigade in Niezhuangzi Commune, Wuqing County fell from the former 40 percent to about 10 percent. Construction by Hujiacun Brigade, Liangwangzhuang Commune in Jinghai County of a leak-resistant ditch linking 12 pump wells has meant an increase in the area watered by each well from the former 74 mu to 150 mu, and an increase in the well-irrigated area from the former 890 mu to 1,800 mu. Second, it saved energy, reducing irrigation costs. Watering of 140 mu of fruit trees through earthen ditches at Qingguang Brigade in the northern suburbs used up 840 kilowatt hours of electricity per watering. After construction of leak-resistant ditches, electricity consumption was 202 kilowatt hours per watering. In some keep well areas, well irrigation areas, mountain areas, and semi-mountainous areas where fields and orchards required much water, following contruction of leak-resistant ditches at multi-level water lifting irrigation stations, economic benefits were even more striking.

In addition, construction of leak-resistant ditches has also prevented secondary salinization of the soil. Furthermore, construction of leak-resistant ditches has meant a saving on land taken for ditches, has enlarged the cultivated area, has reduced silting of ditches, and has saved expenditures and work.

BRIEFS

LIVESTOCK PRODUCTION--Xinjiang Uygur Autonomous Region produced more than 10 million young animals during this year's spring lambing season, hitting an all-time high since the founding of new China. The survival rate of young animals was as high as 94 percent. [OW271241 Beijing Domestic Service in Mandarin 1200 GMT 20 Jun 82]

COTTON GROWING SYMPOSIUM--From 5 to 11 June, the Xinjiang Agriculture Department, the Xinjiang production and construction corps and the regional crop society held a symposium in Shihezi on scientifically growing cotton. The symposium emphatically pointed out that the way of developing cotton production in the region is to stabilize the existing cotton fields, increase the per mu yield and total output, and popularize the technology for growing cotton and raising economic returns. This sumposium discussed the relationship between grain and cotton. The symposium held that after several years' readjustment of the internal agricultural structure, the region must stabilize its areas sown to grain and cotton, the areas sown to grain must not be further reduced and the areas sown to cotton must not be expanded any more. The region must also correct the tendency of attaching more importance to cotton and less to grain. [HK231349 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 22 Jun 82]

FOUR KINDS OF 'SITTING AUTUMN' IN RICE DESCRIBED

Hangzhou JIEFANG RIBAO in Chinese 4 May 82 p 1

[Article: "Kinds of 'Sitting Autumn' in Early Rice"]

[Text] Comrades from the provincial spring farming and production techniques inspection team said the following at a report-back meeting. Because of the large amount of rainfall last winter and this spring, soil maturation has been poor and unfavorable for development of the early rice. Consequently, the possibility that "sitting autumn*" may develop in the early rice crop is very great. In Zhenjiang Province, four different kinds of "sitting autumn" are commonly seen.

First is toxic "sitting autumn." This occurs mostly in fields of high fertility, particularly in green manure fields having more than 4,000 jin of green manure per mu, or in fields where plowing has been overly late (within 7 days of the time when seedlings are transplanted), or where the terrain is low-lying and drainage poor. Prevention and control methods include improvement in drainage and irrigation conditions, lowering the water table, sensible use of green manure, and advocacy of less use of grass seed, with increased applications of quick acting nitrogenous fertilizer raked into the soil surface plus application of gypsum and alum.

The second kind is cold damage sitting autumn. This occurs when seedlings are transplanted too early and low temperatures ensue after transplanting, or when soil temperature is too low. Prevention and control methods include growth of sturdy seedlings with transplanting being done only when average daily temperature has become stable at 15°C. For ridged fields in hills, dtiching around the hill should be done; for cold waterlogged fields, ditching should be done; for fields in general, shallow irrigation should be maintained.

The third kind of "sitting autumn" resulting from lack of some element. This is caused by lack of some nutrient or proportional imbalance of nutrients in the soil. "Sitting autumn" resulting from lack of phosphate or potash is common, and fertilization with phosphate or potash is required. Results are best when at the time of transplanting seedlings roots are dipped or poked into calcium magnesium phosphate. It is more economical to spread phosphate fertilizer on seedlings carrying earth in the seedling fields. At the present time, supplies of chemical phosphate and potash fertilizer are insufficient, so use of barnyard phosphate and potash fertilizer should be vigorously advocated.

---

*"Sitting autumn" (refers to a transplanting phenomenon where transplanted rice seedlings do not grow new leaves or roots while old ones wither or rot. The plant either dies or its growth is retarded 20-40 days.)

Fourth is "sitting autumn" from sodden soil. This occurs in gummy soil, in sodden fields that have been too deeply plowed, and in cold waterlogged fields. After transplanting, seedlings sink and cannot easily put down roots. Prevention and control methods are to dig ditches to divert water, to lower the water table, and to fertilize with phosphate and potash.

The above four kinds of "sitting autumn" frequently occur at the same time, but in all cases it is the roots that are damaged first. Thus it is necessary to increase soil porosity. Once seedlings have been transplanted and have greened up, frequent shallow irrigation should be done. If sitting autumn is discovered, water should be drained away and weeding of the fields done at once together with application of proper amounts of phosphate and potash fertilizer. After weeding has been done, fields should be aired and lightly dried to promote root vitality.

TITLE: "Develop Farming Under the Guiding Principles of Agricultural Ecosystem"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 4, 23 Apr 82 pp 3-8

ABSTRACT: Agricultural ecology is a new science. With the development of agricultural modernization and a closer and closer link between agriculture and industry, such adverse effects on agricultural production as environmental pollution, energy deficiency, and ecological imbalance have also occurred. At present, these problems have attracted widespread attention. This paper introduces the basic concepts of the agricultural ecosystem, which is an offshoot of ecology, a study on the interrelationship between living organisms and their environment. As agricultural yield increase depends upon policy and science, the paper maintains that the good results of policy have been demonstrated by the fast improvement of agricultural production of recent years but science is still needed. By science, the paper means: (1) Reasonable production arrangement to suit the land; (2) Standardization of seed quality and regionalization of superior breeds; (3) Using fertilizer according to the needs of the soil. The above scientific techniques and the development of multiple production structure are explained to be essential in agricultural regionalization according to the viewpoint of the agricultural ecosystem, which should be adopted as the general concept and used as the foundation for implementing agricultural modernization.

TITLE: "On the Strength of Survival of the System of Responsibility With Payment Based on Quota"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 4, 23 Apr 82 pp 20-23

ABSTRACT: The title of the paper as it is translated into English in the journal appears to be less than precise. The system discussed in the paper is in fact a labor responsibility system, practiced universally in the past. In the past 2 years, communes and brigades of many places have changed the labor responsibility system to production responsibility system and very few continue to practice the former. The paper argues in favor of the labor responsibity system because it is favorable for fulfilling the State's plan, for developing the publicly owned properties, and for the full utilization of manpower and natural resources. The two different systems, and perhaps all shades between, are not clearly defined in the paper, however, and the paper does not offer criticisms of the new, and obviously growing, production responsibility system.

TITLE: "The System of Production Responsibility Speeds up the Increase of Large Livestock"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 4, 23 Apr 82 pp 24-27

ABSTRACT: From late Oct to early Dec [1981 ?] the author visited 9 counties in Zhoukou Prefecture of Henan Province and 2 counties of Fouyang Prefecture of Anhui Province to study draft animal related problems before and after the implementation of the production responsibility system. From 1949 to 54, the number of large livestock grew very fast in this part of the country, reaching 908 thousand heads. After collectivization in 1955, there were many changes in the production relationship, and a rush toward public ownership. By 1978, the number of large animals had dropped to 423 thousand heads. In these 25 years, only 1,473 live foals grew up in all of the 40 production brigades of Fugou County. After the adoption of the production responsibility system, doubts lingered. By the end of 1980, the number of large livestock continued to decrease; the number was 1,890 heads less than the end of 1979. In reality, the situation began to turn since 1979, however. In Fouyang Prefecture 104 thousand foals survived, for example. The farmers are willing to pay money to buy draft animals from everywhere in the country. Diseases and the lack of breeding stock are the 2 major problems. The farmers are afraid of possible policy change in the future and they are also afraid of not being able to sell the animals after they raise them.

TITLE: A Preliminary Discussion of the Problem of Energy Resources in Rural Areas of Guizhou Province"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 4, 23 Apr 82 pp 32-36

ABSTRACT: In Guizhou Province, rural energy resources are composed of biological energy of firewood [shrubs and grass] and marsh gas, mineral energy of oil and coal, and natural energy of water and geothermal power. The coal consumption was 19.42 million tons in 1980, amounting to 26.4 percent of the energy consumed that year. Firewood consumption amounted to 72.1 percent of total. The development and utilization of marsh gas and geothermal energy are still in the research stage. To resolve the problem of rural energy needs and to protect the forest resources from further depreciation, the author suggests the following: (1) Reconstruct the existing small hydroelectric power stations to make all the equipment complete and operable. (2) Develop marsh gas in steady steps. (3) Plant trees in the 6,000 mu barren mountains for firewood.

TITLE: "Preliminary Inquiry of Several Problems in the Economic Development of the Animal Husbandry Industry of Xinjiang"

SOURCE: Beijing MINZU YANJIU [NATIONALITY RESEARCH] in Chinese No 2, 20 Mar 82 pp 6-13

ABSTRACT: China is a unified nation of many nationalities. Within the territorial limits, all nationalities cooperate to develop the national resources and to proceed with production for the livelihood and material wellbeing of each as well as for contributing to the civilization of the fatherland. Animal husbandry is the major sector of China's minority economy and is also important in the national economy. It is the material foundation of production and livelihood of the minority nationalities of Xinjiang. It is; therefore, extremely significant for the development of socialism, the prosperity and unity of the nationalities, for the national defense, and for the elimination of de facto inequality among the nationalities. Since the liberation, there has been considerable progress in animal husbandry in Xinjiang. By the end of 1980, the number of animals was reported to be 26.7 million heads, more than doubling that of 1949. Not a few problems remain, however. They include: (1) The need of establishing a scientific concept of cause and effect for the maintenance of ecological balance in the course of developing animal husbandry; (2) The need of emphasizing an internal expansion of reproduction to raise the efficiency of productive material utilization; (3) The need of implementing and perfecting the production

[continuation of MINZU YANJIU No 2, 1982 pp 6-13]

responsibility system to promote a positive feeling toward production among the people who engage in animal husbandry and to raise the labor efficiency; (4) The need of improving the flow of animal husbandry products to promote the development and their production; (5) The need of strengthening the leadership of the party to move forward cautiously and steadily and to realize the fact that peace and solidarity form the basic guarantee for the development of production in animal husbandry.

TITLE: "Conserve the Source of the Water is the Essential Plan of Controlling Changjiang"

SOURCE: Beijing ZHIWU ZAZHI [JOURNAL OF BOTANY] in Chinese No 1, 1982 pp 1-3

ABSTRACT: Changjiang is the largest river of China, measuring 6,300 km. Its drainage basin is 1.80+ million km^2, with 4+ hundred million mu of cropland and 3+ hundred million of inhabitants. Its 700+ tributaries of all sizes measure a total of 80+ thousand km. At present, the forest cover of its basin is shrinking continuously and soil erosion totals 20+ hundred million tons a year. Will Changjiang become the second Huanghe? The current silting problems which are threatening agricultural production, obstructing navigation, and burdening the reservoirs are described. China's scientist ZHU Kezhen [4555 0668 4394] said: "the result of unlimited destruction of forests includes the destruction of soil fertility as well as the sources of water." As flood is the major calamity of the Changjiang Valley, to control the river must start from controlling the mountains. Soon after the liberation, the forest coverage of Sichuan was more than 19 percent. Now it has dropped to 13.3 percent. At present, mud flows are very active in 109 counties of Sichuan Province and mud flow is a form demonstrating the fact that soil and water losses have developed to a very serious stage. The paper calls for forest renewal in the origin of Changjiang in Sichuan Province for the purpose of preserving the Changjiang Valley from further deterioration.

TITLE: "Why is it that Top-pruning Can Increase the Yield of Crops"

SOURCE: Beijing ZHIZAZHI [JOURNAL OF BOTANY] in Chinese No 1, 1982 pp 5-6

ABSTRACT: Top-pruning can increase the yield of cotton about 20 percent, squash more than 30 percent, the castor-oil plant 40-50 percent; the yield increase for rape and sweet potato is even higher. The Jiayu County Institute of Agricultural Sciences of Hubei Province reported a top-pruning experiment in 1972 carried out in 0.22 mu of rape; the average yield reached 540 jin/mu. In 1976, Xinhuang County of Hunan tried the technique in 125 mu of sweet potatoes; the yield of fresh sweet potatoes was 10,000 jin/mu, with the highest reaching 17,800 jin/mu in some of these fields. The paper explains that top-pruning liberates the axillary bud from pressure, improves the photosynthesis efficiency, accelerates the accumulation of nutrients, and increases the number of channels and shortens their distance of nutrient transfer. Essential techniques of top-pruning are also briefly introduced.

TITLE: "Some Ideas Concerning the Assessment of Total Water Resources of the Huai River Plain"

SOURCE: Beijing SHUIWEN [HYDROLOGY] in Chinese No 2, 25 Apr 82 pp 8-12

ABSTRACT: It is a common knowledge that the total water resources of a stream valley include the surface water and the ground water, with the two transforming into one another. With an introduction of the ways of calculating the total water resources of a stream valley before and after the mining of ground water, the method of estimating the surface and the ground water separately before subtracting the overlap and the unavoidable evaporation is recommended to produce the preliminary estimate. The influence of dynamic changes of the water table on the water balance factors is analyzed and the relationship of evaporation of subterranean water, the water requirements of crops, and the ground water resource is explained. The paper emphasizes discussions of the methods and problems of assessing the water resources of a stream valley. There is very little concrete reference to the specific water resources of the Huai River valley.

TITLE: "Application of Computer for Flood Forecasting in Huai River Basin"

SOURCE: Beijing SHUIWEN [HYDROLOGY] in Chinese No 2, 25 Apr 82 pp 21-27

ABSTRACT: Aside from the mountains and hills of the southwest and northeast, the Huai River basin is mainly a broad plain, measuring 270,000 km^2, spanning portions of the 4 provinces of Henan, Anhui, Jiangsu, and Shandong. The upper reaches of the source are short and the flow is swift. The floodwater comes in great force and takes very little time to spread out. The valley is distributed with 5200 large, medium, and small reservoirs, with a total storage capacity of 23 billion m^3. For the purpose of providing forecast information of the floodwater to the minute and second in order to complete the prevention work, the authors divide the entire basin into 8 sectors, 5 of which are located above Hongze Lake. The existing floodwater forecasting scheme is taken as the foundation for arrangement and supplementation to produce 10 systematic floodwater forecasting programs to be processed on a computer; programs are also written for computing the floodwater volume of each sector, the capacity of major reservoirs, the effect of the soils and rainfall so that the forecasting work of the entire basin may be carried out on the computer. The structure of the programs, the computation steps, and the forecasting results using computer are introduced.

TITLE: "On Pollution and Protection of Acidic Pit Water"

SOURCE: Beijing SHUIWEN DIZHI GONGCHENG DIZHI [HYDROGEOLOGY AND ENGINEERING GEOLOGY] in Chinese No 3, 15 May 82 pp 7-9

ABSTRACT: China is extensively distributed with ferric sulfate deposits, coal deposits, and multi-metal sulfide deposits and a large number of these are being mined. The ores contain a certain quantity of sulfides, which, after oxidation, often turn into acidic pit water to corrode the pipes and equipment and endanger the health of the workers. When this wastewater is discharged, it pollutes the environment and the source of water supply to produce serious effects on agriculture, fish culture, and the industries. The chemical process of the formation of the acidic pit water and its characteristics are described. In most cases, the mines of China discharge this type of wastewater without treatment to create serious environmental pollution and great economic losses. In Yuntaishan of Jiangsu Province, for example, the mine discharges 3 thousand tons/month to pollute 1,600 mu of cropland. In an average year, the loss compensation amounts to 50-60 thousand yuan/year, to reach a maximum of 86 thousand yuan/year. Some data of the metal contents of contaminated soil are included also. Major techniques of treating the wastewater to render it harmless and practices of some mines, such as Chuanbu Coal Mine of Jiangsu, are also reported.

TITLE: "On the Origin of Domestic Rabbits and the Development of Rabbit Husbandry in China"

ORG: Nanjing XUMU YU SHOUYI [ANIMAL HUSBANDRY AND VETERINARY MEDICINE] in Chinese No 2, 20 Apr 82 pp 74-76

ABSTRACT: Due to the fact that the bones of rabbits are light and brittle, they are not easily found in nature. Fossil remains hardly exist except in some strata in Spain. It has been proven that all domestic rabbits have their origin in wild cave rabbits of Europe, however their ancestors dwelled in Spain and spread gradually to other parts of Europe and beyond. It is still difficult to pinpoint the time and place of the origin of their domestication, however. It has, nevertheless, also been proven that they were domesticated earlier in China than in Europe. Chinese historical records on domesticated rabbits are introduced. There are many native breeds, mostly white, distributed all over the country but especially in the Chengdu Plain of Sichuan. Domestication of rabbits has had a history of more than 2,000 years in China. In the last century, many breeds have also been introduced from foreign countries. In the 50's and the 70's, there were 2 fast developments. The export of frozen rabbit meat in 1980 amounted to 36,000 tons, 70 percent of the total world trade. The industry is expected to grow very fast in the future, as well.

SOURCE: Nanjing XUMU YU SHOUYI [ANIMAL HUSBANDRY AND VETERINARY MEDICINE] in Chinese No 2, 20 Apr 82 pp 77-79

ABSTRACT: Since the liberation, especially in the recent years, the rabbit husbandry industry has continued to grow. At present, all major products of domesticated rabbits, the fur, the hide, and the meat, are all rated the first in quantity in the world. They have become one of the major export items. Angora rabbit is the most famous. For over 200 years, it has been raised in France, England, Germany, Japan, and China and different lines have been formed and each has its own special charactersitics. In 1978, several herds of Angora rabbits were introduced to China from W. Germany. Each of these can produce 1,500 g of rabbit hair per year. After their arrival, their production is reported to be declining, however. Their body weight is reduced to about 4 kg, and the hair production seldom exceeds 1,000 g. Measures to purify the breed, to utilize foreign breeds for hybridization, and to select and breed new lines are suggested. Problems of the concrete feeding conditions in China, the suitable ratio of a blood line, etc. remain to be answered through practice and experimentation.

TITLE: "Scheme of Regionalization on the Basis of the Dry Hot Wind for Wheat in Shanxi Province"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 4, 20 Apr 82 pp 2-6, 20

ABSTRACT: In some years, a high temperature and low humidity phenomenon appears in the dry hot season between the spring and the summer. It constitutes the major disaster of agricultural meteorology in Shanxi Province to threaten the growth of wheat in its late stage. The yield reduction of wheat caused by this disaster varies from 5-20 percent, as high as 30 percent in some specially severe years. The extent of damage of the dry hot wind on wheat is, of course affected by the time of occurrence and intensity of the wind, but it is also affected by the adversity resistance, the growth and development period, the breed, the healthy growth of the early stage, and the ecological factors of the wheat itself. The paper is prefaced with an analysis of the data of 1959-78 concerning dry hot wind damages to wheat in the various localities of the province and followed with a scheme of dividing the

[continuation of SHANXI NONGYE KEXUE No 4, 1982 pp 2-6, 20]

province into 5 regions, with concrete strategies for protecting the wheat crop in each of these regions.

TITLE: "Yield Increase Effect of Fertilizer Application for Summer Seeded Wheat"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 4, 20 Apr 82 pp 8-11

ABSTRACT: Most summer seeded wheat crops are in hilly upland fields where the soil is thin and the fertilizer is in short supply. For the purpose of clarifying the suitable basic fertilizer, the quantity of additional fertilizer applications, the proper ratio of nitrogen and phosphorus, etc. for such crops, the authors carried out an experiment in small plots to compare 9 different fertilizer treatments. The effects of the different fertilizer treatments on the yield structure, the leaf-area of the wheat colony and the photosynthesis productivity, and the accumulation and distrubution of dry substance are reported. Based upon the result of the experiment, the paper concludes that the yield effect of the optimal combination of fertilizer treatment is to apply 6,000 jin of basic fertilizer [calcium perphosphate + farm fertilizer], 50 jin of addditional calcium perphosphate, and 17 jin of urea. Details of the experiment are given.

TITLE: "Yanbei Prefecture is Suitable for the Development of Flax"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 4, 20 Apr 82 pp 22-23

ABSTRACT: Flax is a tough-bark fiber crop belonging to the Linum Family. There are 3 subspecies under cultivation: the large seed, the small seed, and the medium seed ones. The small seed type is most extensively cultivated. On the basis of utilization, there are the 4 types of fiber-use, oil-use, fiber and oil, and the Putao type. In Yanbei Prefecture, 88 percent of the one million mu of oil crops are oil flax. The seeds are pressed into oil [linseed oil ?] and the dregs are used as feed. The weather of the prefecture is cool and the daylight is plentiful to provide a favorable condition for the formation and accumulation of oil in the plants. At present, the yield is low, about 30-40 jin [seeds ?]/mu. The major reasons are: (1) Under the policy of emphasizing grain crops, lands that are remote, thin, and otherwise poor are allocated for flax; (2) Extensive instead of intensive cropping; (3) Using degenerated breeds. The author argues for a change of policy and the adoption of scientific cropping measures to develop the excellent potential of flax production in the prefecture.

TITLE: "On the Objective Bases of the Suggestion for Making the Xin-Ding Basin into a Region of Concentrated Production of Gaoliang"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 5, 20 May 82 pp 2-3

ABSTRACT: The Xin-Ding basin is located in the north-central part of Shanxi, being a stream valley basin of an elevation of 1,000 m. It encompasses the 5 counties of Xinxian, Dingxiang, Yuanping, Daixian, and Wutai, with more than 2 million mu of cultivated acreage. The weather condition, very favorable for Gaoliang [grain sorghum] and the economic advantages of Gaoliang over other grain crops are discussed. Gaoliang is a soil exhausting crop, however. According to analytical studies, to produce 100 jin of Gaoliang, about 2.5 jin of nitrogen, 1.3 jin of phosphorus, and 3 jin of potassium are required. At present, compared with the condition of the 60's, the organic matter content of the soil in the 70's is generally 0.1 percent less. This is the adverse result of applying only chemical fertilizer without the consideration of nurturing the soil. The people of the Xin-Ding basin also need other grains and cannot concentrate on Gaoliang development unless grains can be supplied from other regions. Scientific research is also deficient in Gaoliang cultivation techniques. The advantages of Gaoliang in the basin are supported with research data comparing heat and photo energy utilization rates of various crops in the basin.

TITLE: "Effects of High Temperature and Seeding Depth on the Germination and Healthy Growth of Summer Wheat Seedlings"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 5, 20 May 82 pp 4-7

ABSTRACT: At present, the major problems of summer-seeded wheat crops, under the high temperature condition, include poor germination rate, weak seedlings, large quantity of seeds for planting, few spikes, and low yield. Ordinarily, the most suitable temperature for sprouting of wheat seeds is 15-31°C. When summer wheat is seeded in early July, the average temperature is above 24°C. It may be as high as 30-35°C. A study is carried out to determine the effect of simulated temperature conditions between 21 and 40°C on the germination of wheat seeds, the nutrient consumption within the seed, and the growth of radicles, etc. The study also includes varying depth of seeding from 3.97 to 8.94 cm. It is the conclusion of the study that the suitable seeding depth for summer wheat is 3.5-4.0 cm. Detailed techniques of promoting germination and healthy growth of seedlings are reported.

TITLE: "Several Problems Concerning Summer Seeded Wheat"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 5, 20 May 82 pp 7-8

ABSTRACT: Summer seeded wheat is developed as a reformed cropping technique for upland wheat culture of mountainous and high altitude regions. The variation of production conditions in Shanxi is largely the result of different meteorological conditions of the different regions. It is; therefore, important to understand the suitability of the local weather condition for summer seeded wheat before it is developed locally. When the same breed of wheat is seeded in the summer instead of spring, the height of the stalk is lower, the number of nodes is reduced, the tillering node is moved to 2-3 cm, instead of 5-7 cm, from the ground surface, the growth and development period is shortened, and the flag-leaf-age is delayed to 55 days instead of the normal 40+ days. The seeding time is a key problem of wheat. If it is seeded early, the extended period of high temperature is not favorable; if it is seeded late the frost may affect normal ripening. It is the preliminary conclusion of the author that summer wheat in Shanxi should be seeded from late Jun to early Jul. About 25-30 jin of seeds should be planted, with not very thick soil cover. About 1 cun below the surface is the best. When additional fertilizer is applied, the ripening stage is delayed; therefore, the author suggests that one application of sufficient basic fertilizer is the best for summer seeded wheat.

TITLE: "Correct Treatment and Scientific Utilization of Farm Chemicals"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 5, 20 May 82 pp 21-23

ABSTRACT: According to survey data, the province has more than 580 types of pests and more than 200 types of plant diseases. There are two attitudes toward farm chemicals. Some think they are all powerful and spray them as soon as pests are observed. Others are terrified when the word pesticide is mentioned. The paper attempts to discuss rationally the following 3 problems concerning pesticides: (1) The problem of resistance of the pests: It is necessary to determine scientifically the development of resistance of a given pest and different pesticides should be rotated to prevent the development of resistance. (2) The problem of destroying natural enemy of pests: The use of highly selective or internal absorbing chemicals and the technicque of low density spraying should be adopted to avoid killing natural enemies of pests. (3) The problem of pesticide residues: The safety regulation of the State concerning various chemicals must be strictly followed.

TITLE: "Reasonable Crop Arrangement Should be Given Attention in the Extension of Superior Breeds of Paddy Rice"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 5, 17 May 82 pp 7-9

ABSTRACT: Since the liberation, there have been, generally speaking, 3 stages in the work of extending superior rice breeds: The first stage of 1949-62 is to improve and replace farm breeds; the second stage of 1963-74 is to use dwarf breeds to replace high-stalk breeds; the third stage from 1975 on is to begin to extend hybrid paddy rice breeds. As each stage develops, a yield increase breakthrough has been obtained and the superior breeds of that stage are kept stable for a period of time. Within each of the period of relative stability, if the yield increase is to be sustained, a reasonable crop arrangement must be found, however. This paper reports the experience of Shaoguan Prefecture in Guangdong Province of recent years. The intermediate ripening breeds of Zhaiyeqing, Qingeai are arranged partially with some early and late ripening breeds for the early rice crop. For the late rice crop, hybrid rice and early ripening breeds are extended, to be arranged partially with intermediate and late ripening breeds. In the 3 years, a grain yield increase of 5.6 percent per year has been obtained for the entire prefecture. In 1979, the year's average reaches 970 jin/mu, averaging a grain ration of 579 jin per inhabitant. Details of this experience are reported.

TITLE: "Method of Preventing Mixing and Preserving Purity for Geng Rice Three-lines"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 5, 17 May 82 pp 8-9

ABSTRACT: For several years, such Geng hybrids as Liming-A and Fengjin-A have been used in large acreages in Liaoning Province. When bags are used, the inbred fruiting rate is 0.017-0.06 percent and the sterility characteristic is basically stable. As the acreages are enlarged, there is not enough time for renewal of seeds of the 3 lines, and the phenomena of mixing and degeneration of the sterile line and the hybrid seeds are observed, mainly in the lack of uniformity of stalk height, spike type, ripening time, and the characteristic of bearded, beardless, long beard, or short beard. Measures adopted to purify the 3 lines and to prevent further mixing are reported. The fact that the technique of preventing mixing and purification for the 3 lines of Geng rice is somewhat different from the technique for Xian hybrids is the major aim of the paper yet the difference is not clearly demonstrated.

TITLE: "Strengthen Cotton Bud Stage Management to Guarantee Stable Growth and to Increase Number of Buds"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 5, 17 May 82 pp 12-13

ABSTRACT: In the cotton bud stage, the growth of the root system reaches the peak and that of the above ground portion accelerates. The cotton plant changes from nutritional growth to reproductive growth and 50 percent of the growth of the main stem, about 70 percent of the **fruiting branches**, and about 60 percent of the total number of buds must be completed in that stage. The management requirements are to irrigate and drain to prevent either flood or drought, to apply a balanced amount of nitrogen, phosphorus, and potassium fertilizer according to the appearance of the plants, to hoe deeply to loosen the soil and to eliminate weeds, and to control pests thoroughly. The paper also recommends spraying several times with cycocel but it should be diluted to a low density.

TITLE: "Application of Shachongshuang for the Prevention and Control of Rice Pests"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 5, 17 May p 22

ABSTRACT: Shachongshuang [sodium thiosulfate propane ?] is a highly effective, broadspectrum, safe, low toxic, and low residue pesticide developed in China in the 70's. Toxicity tests have proved it to have no carcinogenic, mutagenic, or deformity causing actions. It is chemically stable, may be stored in room temperature, and remains highly effective a year later. It is both a contact and an internal absorbing pesticide. It can also be used as a fumigant and can kill pest eggs. Experience of applying 25 percent Shachongshuang in the county last year to prevent and control late rice leaf roller, rice thrips, rice leafhopper, rice plant skipper, rice planthopper, rice striped borer, etc. is reported. This new pesticide is the product of Liyang Chemical Plant of Jiangsu Province. The plant received a national science award for the successful research in 1978. At present, the Taihe County Agricultural Chemical Plant of Jiangxi Province is producing several hundred tons of it every year. It is being sold on the market at 1.85 yuan per jin.

ABSTRACT: According to foreign reports, Yersinia enterocolitica is extensively distributed in nature and when it is distributed in the digestive tract of men and animals, it may cause enteric infectious diseases. A large portion of infant diarrhea is caused by this germ and from time to time an epidemic may erupt. Isolation of this germ had not been reported before in China. The authors proceeded with Yersinia enterocolitica culture of 88 specimens of ileocecal contents of pigs slaughtered at the Henan Provincial Meat Joint Plant. Sic strains of Yersinia enterocolitica were isolated. Biochemical, morphological, biological typing, etc. identification processes were also performed. Details of the 1980 experiment are reported.

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] in Chinese No 2, 22 Feb 82 pp 20-22

ABSTRACT: Since 1977, swine toxoplasmosis has been discovered off and on in many places in China. For diagnosis, aside from using pathogen isolation and morphological observation, some scientists have now applied the immnuofluorescence technique, enzyme labeling method, etc. to ascertain the pathogen. Meanwhile, immunoserological diagnosis techniques are also being gradually developed, including pigment test, indirect blood cell agglutination test, abnormal skin reaction, etc. In the past year, the authors used indirect blood cell agglutination test to examine 223 serum antibody specimens of swine toxoplasmosis cases. Of these, 76 specimens were from vaccinated pigs, the positive rate was found to be 100 percent; 29 from healthy pigs, the positive rate was 93.8 percent. The technique was found to be highly sensitive, fast, and simple, and should be feasible for the purpose of conducting general surveys. The technique is introduced.

TITLE: "Blending Experiment of Swine Erysipelas and Swine Pulmonary Bacillus Protoplasms"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 4, 20 Apr 82 pp 2-7

ABSTRACT: Cell blending is a new technique developed in early 60's. Further studies are still awaited regarding improvement of blending technique, survival of the hybrid cells, selection, and heredity, etc.,however. Swine erysipelas and swine pulmonary bacillus are two of the most serious pathogens of infectious diseases endangering the animal husbandry industry, although weak vaccines of both have been successfully cultured to treat them. An experiment is carried out by the authors using PEG to induce blending of protoplasms of both pathogens. The experiment, repeated numerous times, indicates that the method is feasible, but the protoplasms should not be treated with the 40 percent PEG for too long a period of time. Details of the experiment are reported.

TITLE: "A Survey of Swine New Fever"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 4, 20 Apr 82 pp 34-38

ABSTRACT: In Jun 78, several herds of piglets were purchased from a certain swine seed farm in Hubei Province and transported to Chengdu City and neighboring counties of Sichuan Province. Hog cholera and paratyphoid vaccinations were administered before the shipment. Symptoms of diarrhea and fever occurred repeatedly to the piglets; the incidence was high but the mortality rate was low, yet there were also occasional cases of acute infection and sudden death. Is this hog cholera? Is it toxoplasmosis? Moreover, in Dec 78, one hog in Guanghan, which came to Sichuan with the aforementioned herds, came down with the same symptoms. It was dissected and Toxoplasma gondii was not found. The epidemic condition, the pathogenetic signs, and variations of symptoms of this disease are reported. A type of micro-nodules, capable of twisting, were found to be in all the tissues, body fluids, and excretions of the diseased pigs. This disease temporarily named a paratoxoplasmic disease which has later been changed to the temporary name of new fever.

TITLE: "The Hydridoma Technique and Its Application"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 4, 20 Apr 82 pp 41-45

ABSTRACT: The hybridoma technique was established in 1975 by Kohler and Milstein. It is a type of genetic engineering method of producing monoclonal antibody, and has attracted a great deal of attention in foreign countries. Hybridoma companies have been created in the USA with giant capital investments. In China, this sort of technology is relatively backward, especially with regard to its application in veterinary medicine. There has yet been any introduction in domestic journals or books. Based upon foreign data related to the subject, this paper introduces briefly the hybridoma technique of making monoclonal antibody and the applications of monoclonal antibodies in immunological research, in microbiological classification, and the prospect of their application in clinical treatment of cancer and other diseases. The paper does mention the fact that research on hybridoma has begun in China, but does not give any details.

PRC REGULATIONS ON WATER, SOIL CONSERVATION

OW080101 Beijing XINHUA Domestic Service in Chinese 0032 GMT 7 Jul 82

[Text] Beijing, 7 Jul (XINHUA)--The State Council promulgated the "Regulations Governing the Work of Water and Soil Conservation" on 30 June 1982. The regulations read in full as follows:

Chapter I: General Principles

Article 1

The prevention and treatment of soil erosion and the protection and rational use of water and soil resources are a fundamental measure to transform hilly, mountainous, windy and sandy areas; harness rivers; reduce the natural disasters of flood, drought and sand blown by the wind; build a good ecological environment and develop agricultural production as well as an important aspect in harnessing the land of our country. To perform water and soil conservation work well, these regulations are hereby laid down.

Article 2

The principles guiding the work of water and soil conservation are to lay equal stress on both prevention and treatment, combine harnessing with management, suit measures to local conditions, make overall plans, tackle problems in a comprehensive way, eliminate what is harmful and promote what is beneficial.

Article 3

The Ministry of Water Conservancy and Power is in charge of water and soil conservation work throughout the country. A group for coordinating water and soil conservation work throughout the country shall be set up with the Ministry of Water Conservancy and Power as the leading factor and with the participation of the state planning commission, the state economic commission, the Ministry of Agriculture, Animal Husbandry and Fishery and the minister of forestry in order to strengthen the liaison with various departments concerned, regularly study and solve major problems in water and soil conservation work and do this work well. Local people's governments at various levels that are tasked with the prevention and treatment of soil erosion should set up necessary organizations for water and soil conservation according to their specific conditions.

The tasks of water and soil conservation organizations are to carry out the principles, policies and decrees of the state on water and soil conservation; conduct water and soil conservation surveys; make plans for water and soil conservation and organize the implementation of such plans; supervise and check up on water and soil conservation work by the departments concerned; organize and engage in scientific research on water and soil conservation, the training of qualified personnel and propaganda work in this regard; and do a good job in managing and using funds and materials for water and soil conservation.

Various river valley organizations should be responsible for surveying, planning and engaging in scientific research on water and soil conservation in their own valleys and assist and give impetus to the water and soil conservation departments of various provinces, autonomous regions and municipalities directly under the central government in their valleys in performing water and soil conservation work well.

Water and soil conservation, agrotechnical, forestry, water conservancy, farm machinery, clay fertilizer and prairie stations are all dutybound to help local communes and production brigades and teams with water and soil conservation work.

Article 4

People's governments at various levels in hilly, mountainous, windy and sandy areas must include water and soil conservation in their plans, strengthen their leadership, make overall plans, organize and coordinate the work of water and soil conservation, conduct propaganda and education, and mobilize the masses to do this work well. Water conservancy, agricultural, forestry, animal husbandry, land reclamation, environmental protection, railway, communications, industrial, mining, power, scientific research and other departments must closely coordinate with each other, divide their work with individual responsibility and perform their water and soil conservation work well. Propaganda and publication departments should make propaganda on water and soil conservation in a planned way, popularize scientific knowledge in this regard and raise cadres' and people's understanding of the harmfulness of soil erosion and the importance of water and soil conservation.

Article 5

Under the guidance of overall planning for water and soil conservation by local people's governments, rural communes, production brigades and teams, as well as state farms and state forest and livestock farms should make concrete plans for water and soil conservation according to local natural conditions and the actual needs of the masses in production and livelihood, and organize the implementation of such plans.

Article 6

It is necessary to mobilize social forces and rely on the efforts of the masses to prevent and treat soil erosion. The state will give necessary financial and material aid to them and provide key areas with additional aid.

Planning departments at various levels should include water and soil conservation in their economic plans. The special funds allocated by the state for water and soil conservation must be used for this special purpose, not for other purposes. Water and soil conservation and finance departments at various levels should strengthen their management of funds and attach importance to returns on investment.

Chapter II: Prevention of Soil Erosion

Article 7

It is forbidden to open up and plant crops on slopes with a gradient of more than 25 degrees. The people's government of provinces, autonomous regions and municipalities directly under the central government may stipulate a gradient of less than 25 degrees based on local terrains, landforms and population density which also forbids the opening of a slope.

Article 8

It is forbidden to open up wasteland, scoop up sand or cut into a mountain with explosives for quarrying in seriously windy and sandy areas, areas with the danger of a landslide, areas where a mud rock flow is possible, on hillsides along railways, highways, rivers and irrigation ditches and in areas around reservoirs, natural protection areas, scenic areas and places of historic interest, scenic beauty and important cultural heritage.

Article 9

It is forbidden to reclaim wasteland in Loess hills and gullies as well as plateau gullies on the Loess plateaus. The provinces and autonomous regions concerned should, according to their specific conditions, stipulate areas that it is forbidden to reclaim.

Article 10

It is strictly forbidden to destroy forests, open up wasteland and reclaim grasslands and slopes for grazing livestock.

Article 11

In opening up land on slopes with a gradient of less than that which forbids the reclaiming of a slope, a unit or individual must obtain the approval of a people's government at the country level and take measures for water and soil conservation. Violators of this article shall be ordered to return the reclaimed land planted with trees and grass.

In opening up land on slopes with a gradient of less than that which forbids the reclaiming of a slope, state farms must report their plans to higher authorities for approval in accordance with relevant state regulations. The land reclamation plans which they submit to higher authorities for approval must include implementation plans for water and soil conservation. The state farms should also solicit opinions on their implementation plans from water and soil conservation departments before their land reclamation plans are approved. After their land reclamation plans are approved, the water and soil conservation departments should supervise the implementation of such plans.

Article 12

Indiscriminate felling of trees to the damage of water and soil conservation is strictly forbidden. Plans for felling trees in accordance with state regulations that are submitted to higher authorities for approval must include implementation plans for reforestation on slashes and for water and soil conservation. Opinions on the implementation plans should be solicited from water and soil conservation departments before the tree-felling plans are approved. After the tree-felling plans are approved, the water and soil conservation departments should supervise the implementation of such plans.

Article 13

In afforesting slopes, weeding and intertilling the land between young trees and replanting hillsides with tea oil and tung trees, it is necessary to take water and soil conservation measures in order to prevent soil erosion.

Article 14

In building projects or engaging in production in hilly, mountainous, windy and sandy areas, water conservancy, railway, communications, industrial, mining, power and other departments should minimize damage to landforms and vegetation. In quarrying, digging up clay and scooping up sand which may cause soil erosion, it is essential to take water and soil conservation measures. Discarded clay, rocks, sand, slag and tailings must be properly disposed of and must not be allowed to be dumped into rivers and reservoirs. When a project is completed, the construction unit is responsible for taking vegetation measures and necessary engineering measures to protect water and soil resources in the uncovered areas from which the unit dug and took clay.

Engineering project designs and production plans submitted by various departments for approval must include measures for preventing and controlling soil erosion. Opinions about such measures must be solicited from the department in charge of water and soil conservation work prior to the approval of the designs and plans. After the approval of the designs and plans, the measures must be implemented under the supervision of the said department. Where soil erosion has already appeared, control measures must be taken within a certain time limit. Funds required for soil erosion control should be disbursed from the capital construction investment in the case of capital construction units or from the money set aside for equipment renewal and the streamlining of enterprises or, in the case of production enterprises, from the fund for developing production.

Article 15

County [prefecture?] governments in mountainous and hilly areas and in windy and sandy areas should organize the rural communes and production brigades as well as the state-run agricultural, forestry and livestock farms according to local conditions and in a planned way to close certain mountains and hills for the purpose of averting the erosion of sandy soil, plant trees and grow grass, close certain areas and use other areas as grazing lands on a rotational basis and vigorously build fuel forests and grow fodder grass and green manure crops. Habits such as removing sod, digging up tree saplings [Wa Shu Dou 2177 2885 0351], indiscriminate logging and wanton grazing should be changed in order to protect vegetation.

Article 16

County-level people's governments in mountains and hilly areas and in windy and sandy areas should, in accordance with the needs of production plans and water and soil conservation, work out specific measures in order to lead--in a well-organized way--the work of the various sideline production projects of rural communes and production brigades, state-run agricultural, forestry and livestock farms and individuals, such as collecting and growing medicinal herbs, raising tussahs, cultivating edible fungi and mushrooms, making charcoal, bricks and tiles, mining and quarrying. It is necessary to prevent random digging or dumping of earth and rocks, a practice which can destroy vegetation and result in soil erosion.

Chapter III: Soil Erosion Control

Article 17

In controlling soil erosion in mountainous and hilly areas, it is necessary to act in accordance with the local natural conditions, take small river valleys as units for such work, make overall plans, apply diverse methods, concentrate attention and make continued efforts. It is necessary to combine measures concerning plants with engineering measures, work on mountain and hill slopes with work on ditches and water channels, and engineering projects in the fields with farming measures aimed at conserving water and soil. In addition, it is necessary to pay attention to both controlling soil erosion and promoting production by utilizing natural resources, take into consideration both immediate and long-range advantages and strive for practical results.

Article 18

As for present arable sloping land, if the slope is above the degree for banning reclamation, it should be treated discriminately according to the different conditions. If local communes and production brigades have relatively few people but large expanses of land, they should actively build their basic fields on flat and less sloping land and do their best to raise the per unit output from such fields, while using the more sloping land for building forests and growing grass instead of farming. If the local communes and production brigades have relatively large numbers of people but small expanses of land and, therefore, find it difficult not to farm on their arable sloping land, it is necessary to set a time limit, according to the degree of slope, for them to build the sloping land into terraced fields or to take other measures to conserve this land's water and soil. As for present arable sloping land where the slope is less than the degree for banning reclamation, it is necessary to take such water and soil conservation measures as contour farming, contour listing, rotation of grass and field crops and the building of terraced fields in order as to prevent and control the soil erosion.

Article 19

Local people's governments should organize the forces of communes, production brigades and the masses to carry out the task of controlling soil erosion by taking into consideration how the agricultural production responsibility system is being carried out and by adopting appropriate measures that are best suited to local conditions.

Communes and production brigades that should cooperate with each other in fulfilling their heavy tasks of controlling soil erosion are required to carry out the principles of voluntary participation and mutual benefit, exchange based on equal value and reasonable responsibilities. After commencement of the soil erosion control project, the task of management, distribution of benefits and use of the newly added farmland should be decided by the participating units through discussion. The ownership of the original land should not be changed.

Article 20

Rural communes and production brigades and departments concerned should make all-out efforts to build necessary tree sapling farms and seed production bases so as to supply grass seeds and tree saplings required for controling soil erosion.

Article 21

Any unit or individual who has caused soil erosion because of land reclamation, sideline production projects, mining, road construction, building of water conservancy or hydroelectric power projects, logging or other production and construction projects should be responsible for solving the soil erosion problem. The local people's government has the power to supervise, speed up, inspect and set a time limit for the work in this regard.

Article 22

All localities should fulfill the responsibility for the management of water and soil conservation facilities (including engineering projects as well as trees and grass). All localities should strengthen the management and maintenance of these facilities, increase their benefits and give full play to their role in conserving water and soil.

In accordance with the state of water and soil conservation facilities, rural communes and production brigades should fulfill the responsibility for their management and maintenance. For some water and soil conservation facilities, pledges for their management and maintenance may be drawn up and necessary management and maintenance organizations may be formed. Conservancy, railway, communication, industry and mining departments, as well as state-run agricultural, forestry and livestock farms, should set up management and maintenance organizations or assign specific personnel to take care of the management and maintenance of water and soil conservation facilities within the scope of their jurisdiction.

Article 23

No unit or individual is allowed to encroach upon or sabotage water and soil conservation facilities or experimental spots, instruments or equipment for water and soil conservation.

Article 24

In the windy and sandy areas of northeastern, northern and northwestern China, the local people's government should, under the state's unified planning, organize rural communes and production brigades as well as state-run agricultural, forestry and livestock farms to build windbreaks and to concentrate on growing grass over large tracts of land in order to protect against wind and avoid the erosion of sandy soil. In other windy and sandy areas, the local people's government should also work out plans and take effective measures to prevent the harmful effects of wind and sand.

Article 25

With regard to grasslands, grassy mountains and grassy slopes which have become sandy and degenerated, it is necessary to adjust the number of livestock grazing there in a planned way based on the livestock accommodating capacity of these areas. It is also necessary to apply the measures of closing certain areas and using other areas for grazing on a rotational basis, sowing fodder grass and building windbreaks in an effort to restore vegetation and improve the conditions of the grazing land. In areas with serious soil erosion, active efforts should be made to grow fodder grass, promote the method of raising livestock in confined areas and change the practice of open field grazing in order to restore vegetation.

Article 26

In areas where the people have the habits of reclaiming mountain land for farming [Dao Shan Lun Zhong 0227 1472 6544 4429] and cutting or burning off grass and trees to do farming [Dao Geng Huo Zhong 0430 5087 3499 4429], the local people's governments should strengthen propaganda and education, assist in building basic farmland, popularize agricultural science and technology and create various conditions for changing the farming habits step-by-step in the interest of water and soil conservation.

The sloping land not being used in rotational farming should be promptly planted to fodder grass or green manure crops in order to increase the vegetation on the land.

Chapter IV: Education and Scientific Research

Article 27

Education, water conservancy, agricultural and forestry departments should sponsor a specialty class or course on water and soil conservation at related institutions of higher learning. Provinces and autonomous regions with serious soil erosion problems may establish secondary water and soil conservation schools or set up a water and soil conservation speciality class or course at secondary water conservancy, agricultural or forestry vocational schools for the prupose of vigorously training scientific and technical workers in this field. Relevant courses at primary and middle schools should contain something about water and soil conservation.

Article 28

The Chinese Academy of Sciences, the departments of water conservancy, agricultural and forestry research, the water and soil conservation departments of provinces, autonomous regions and provincial level municipalities and the river basin management organizations should strengthen leadership over their subordinate scientific research units which handle water and soil conservation. They should seriously conduct scientific research on water and soil conservation and timely summarize and popularize the results of this research.

Scientific research on water and soil conservation must be conducted in close connection with reality in order to serve the prevention of soil erosion and the development of production, while research is conducted on major practical techniques for water and soil conservation, it is also necessary to do intensive research on basic theories and relevant social and economic problems in order to produce scientific data for preventing soil erosion.

Chapter V: Rewards and Punishment

Article 29

Organizations or individuals that perform any of the following advanced deeds shall be commended and rewarded according to their accomplishments by the people's governments at various levels:

1. Making outstanding achievements in the prevention of soil erosion or in the management and maintenance of water and soil conservation facilities;

2. Persistently doing fast and good repairs of soil erosion and performing water and soil conservation with remarkable economic results for a long time;

3. Achieving noticeable achievements in actively changing the habit of extensive cultivation, conserving water and soil and developing agricultural, forestry and animal husbandry productions;

4. Making fairly large inventions, innovations or other contributions in the science and technology of water and soil conservation;

5. Achieving remarkable successes in the research, education, publicity and popularization and management of water and soil conservation science;

6. Making contributions in the struggle against the sabotaging of water and soil conservation; and

7. Doing water and soil conservation work at the grassroots level for more than 15 years with enthusiasm and outstanding performance.

Article 30

Organizations or individuals that commit any of the following violations of these regulations should be held responsible for compensating for the loss; the responsible persons of the organization or the individual violators should be handled with disciplinary sanctions; and investigations should be conducted on those who commit crimes in order to affix the responsibility for the crimes:

1. Reclaiming wasteland in violation of articles 7, 8, 9, 10 and 11 or refusing to follow water and soil conservation measures and thus causing serious consequences when reclaiming land on slopes which are officially open to reclamation;

2. Refusing to reforest slashes or prevent soil erosion in violation of articles 12 and 13 and thus causing serious soil erosion;

3. Refusing to follow water and soil conservation measures in violation of article 14 and thus causing damages due to soil erosion;

4. Wantonly excavating or dumping earth and stone or destroying vegetation when undertaking sideline production and thus causing damages due to soil erosion; and

5. Seizing or destroying water and soil conservation facilities, experimental spots, instruments and equipment in violation of article 23.

Article 31

All organizations and persons have the right to report to authorities or file charges against those who violate these regulations. The reported or accused organizations or individuals shall be punished according to law if they take reprisals.

Chapter VI: Supplementary articles

Article 32

The people's governments of various provinces, autonomous regions and provincial level municipalities may formulate detailed rules and regulations based on these regulations.

Article 33

These regulations come into force upon promulgation.

BEIJING

TIPS PROVIDED FOR GROWING NEW CORN VARIETY

Beijing ZHONGGUO NONGMIN BAO in Chinese 13 May 82 p 4

[Article: "Early Maturing Corn, 'Jingzao No 7'"]

[Text] "Jingzao No 7" is a single cross variety of corn bred by the Beijing Municipal Academy of Science's Crop Institute. Its female parent was Huangzao 4 and its male parent was Luoxi 3. It is characterized by early maturation, high yields, and resistance to disease. Since 1979 it has been promoted for cultivation throughout the country over an accumulated more than 4 million mu, for a 450 million jin increase in grain output. This year it has been made a major project for promotion throughout the country.

Jingzao No 7's growing season is about 95 days, making it suitable for sowing in the summer or planted in spring following the wheat harvest on the northern part of the North China Plain. He'nan and Shandong are now test planting it for promotion, and a certain acreage has also been devoted to it in Sichuan and Hunan. It may very possibly become a wetland rotational crop in the mid and lower reaches of the Chang Jiang, and a variety with prospects for changing the farming system there. When sown in spring in cold areas, it is prone to development of head smut, requiring that disease prevention measures such as late sowing and mixing of seeds in pesticides be taken.

Jingzao No 7's main characteristics are compactness of plant shapes, and an upward tilt of middle and upper leaves that permits close planting. Its hollow stalk rate is very low, and its double ear rate may reach as much as 10 to 20 percent. Yields average 600 to 700 jin per mu, the maximum being 1,300 jin or so. Yields from 59 high-yield demonstration fields in the Beijing suburbs in 1981 averaged 1,012.5 jin per mu. Jinzhuang Production Brigade in Gaocheng County, Hebei Province harvested average yields of 1,120 jin per mu from 120 mu.

Other characteristics of Jingzao No 7 are as follows: Resistant to large and small leaf spot; tolerates waterlogging and is drought resistant; has fairly wide adaptability. Kernels are almost hard, and both quality and taste are rather good. Plants do not prematurely deteriorate during the late stages of development, and at harvest time between 3,000 and 4,000 jin per mu of fresh stalks and leaves may be taken. For both parent pairs the inbred line shape characteristics are apparent. Plant colonies readily differentiate, making for ease in getting rid of mongrels to preserve purity. Additionally, the leaves of the female parent inbred line, Huangzao 4, stick up, and its double earing rate is very high. Actual density of plants is 5,000 to 5,500 per mu and seed production stands around 300 jin per mu, making for rapid promotion of this variety to cultivation.

The growing of Jingzao No 7 requires mastery of three key techniques:

1. Early sowing. Jingzao No 7's leaves total 22 in number and it requires cumulative temperatures of from 2,350 to 2,400°C during its growing season. When it is fully ripe, the per 1000 weight of kernels is more than 300 grams. However, because it is frequently planted late in production, and unable to ripen normally before fall planting begins, its per 1000 grain weight is only about 250 grams. Thus, a potential for increased yields of more than 100 jin per mu exists. Consequently, efforts should be made to plant early to assure that there will be plenty of time for kernels to be in-the-milk during the late stage. When grown during the summer in the Beijing-Tianjin area, it should be planted no later than 24 June.

2. Suitable close planting. When grown in soils of moderate to high fertility, seedlings should best be thinned to 4,100 - 4,300 per mu for an actual harvest of 3,800 - 4,000 stalks.

3. Increased fertilization. Summer corn has a short growing season. It grows rapidly; yields are high; and it has to absorb greater amounts of nutrients. Fields that produce 700 - 800 jin per mu generally require 80 - 100 jin per mu of ammonium carbonate, fertilization being done twice, after the thinning of seedlings and during the time of full flowering, following the principle of "heavy application first and light application later." For high yield fields producing upwards of 1,000 jin per mu, fertilization with nitrogen should be increased to 120 - 150 jin per mu.

NEW PROGRESS IN AGRICULTURAL ZONING IN FUJIAN PROVINCE

Fuzhou FUJIAN RIBAO in Chinese 10 Apr 82 p 3

[Article by FUJIAN RIBAO correspondent: "Agricultural Zoning in Our Province Made New Progress"]

[Text] Resource survey and agricultural zoning in our province made new progress last year. By now, 30 counties, or 43 percent of all the counties and municipalities in the province, have begun these tasks, and five of them--Putian, Shouning, Changding, Shaxian and Shunchang--have already completed or basically completed them.

Last year, thanks to the attention of the provincial, prefectural and county leading departments and the efforts of the broad masses of scientific and technical personnel, the work of agricultural resource survey and agricultural zoning in our province has developed from exploration in a few selected counties to experiments in many far-flung points. There are now experimental counties in all nine prefectures and municipalities. All these counties have selected a large number of cadres and agricultural scientists and technicians for training backbone elements in technology. They were organized into specialized investigation groups for agriculture, forestry, animal husbandry, fishery, meteorology, water conservation, farm machinery, hydrology, geology, and enterprises run by communes and production brigades. They visited the mountainous and hilly regions, the plains and coastal areas to investigate and ascertain the availability of natural resources. In Putian County, it was discovered during the investigation that more than 220,000 mu of barren hills have not yet been utilized; that more than 120,000 mu of shallow sea and beaches could be used for breeding purposes; and that this county had favorable locations for growing sugarcane and the three famous fruits (longan, litchee and loquet). Instead of worrying about the difficulty of developing production in view of the scarcity of land and the large population, as they did for a long time in the past, the broad masses of cadres and people can now see the bright prospects for developing the mountainous and sea areas. In Shouning County, it was discovered that there were rich resources in the form of wild peaches, which, if properly attended to, could yield 200,000-300,000 dan of fresh fruits and become a source of good income.

Through the survey on agricultural resources and agricultural zoning, many localities are now able to direct their agricultural production purposefully instead of blindly, and have organized the communes and production brigades to turn their attention to the mountains and the sea.

BRIEFS

FLOWER-GROWING COMMUNE--Some educated young people in (Yongfu) commune of Zhangping County, a famous flower-growing village in Fujian province, have been praised by the leading cadres of the Fujian Provincial Party Committee for their success in growing flowers and cultivating precious flower varieties. Their products are sold in 16 provinces and cities in China. Xiang Nan, first secretary of the Fujian Provincial Party Committee, visited (Yongfu) commune on 14 June. He said to prefectural, county and commune cadres: (Yongfu) is a good place. It is necessary to do good planning and continue to develop flower production. BRIEFS

COUNTY LIVESTOCK--Xiahe County, Gansu Province, achieved good results in spring livestock production. Now the number of livestock production totals 1.01 million head. All of the 270,000 head of newborn lambs and calves are growing well. [SK052258 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 4 Jul 82]

GRASS PLANTING MEETING--The Gansu Provincial animal husbandry and agricultural departments recently held a meeting in Tongwei County on planting grass in dry areas in the central part of the province. The meeting contended that planting grass and raising animals in dry areas in the province is the best way to fertilize the soil to promote bumper harvest in agriculture and animal husbandry. Attending the meeting were responsible comrades of 18 counties which have dry lands and provincial and prefectural pertinent departments. They visited some production team grasslands and exchanged experiences in grass planting. [SK030730 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 2 Jul 82]

RAPID PROGRESS OF WHEAT-SOWING REPORTED IN HEILONGJIANG

Harbin HEILONGJIANG RIBAO in Chinese 12 Apr 82 p 1

[Article by HEILONGJIANG RIBAO correspondent: "Wheat-sowing in Our Province More Than Half Completed"]

[Text] Because of the fine weather in various parts of the province in the past several days, wheat-sowing has been carried out at the rate of 600,000 mu each day. By 9 April, 15,600,000 mu, more than one-half of the total planned acreage, or 3,770,000 mu more than the acreage in the same period last year, had already been sown to wheat.

There was serious waterlogging in the eastern part of the province this spring. All farms and production teams carried out sowing on a crash basis and won the initiative. All units in the wheat producing areas of the west and the north increased their sowing speed by preparing the farmland and attending to the problem of moisture simultaneously in the effort to achieve a high yield. Throughout the province, some 4.8 million mu of land had been leveled and thoroughly raked before the actual sowing. In the two wheat areas in the west and the north, sowing is now in the peak period and the rate of progress is faster than in past years. It is anticipated that by 20 April, or thereabout, more than 90 percent of the work will be completed.

The farmland is now full of moisture everywhere. While sowing in the hilly areas on a crash basis, people in all wheat growing areas are continuing to prepare the land by turning over the top soil or by breaking down the ridges as a means of dissipating the moisture, in an effort to plant more wheat in the lowland. The relevant departments directly under the province are supplying more seeds for the late crop to the farms and production teams where waterlogging is serious, so that they can carry out their sowing at a later stage.

SYSTEMS OF OWNERSHIP IN HEILONGJIANG RECLAMATION AREAS DISCUSSED

Harbin HEILONGJIANG RIBAO in Chinese 12 Apr 82 p 1

[Article by correspondent: "Reclamation Area Economy Developing in the Direction of a Diversified Ownership System"]

[Text] The reclamation area economy in our province is now gradually developing in the direction of a diversified ownership system. At present, there are 1,457 collectively-owned (production team) enterprises with some 110,000 workers and staff members in the reclamation areas, and the number of households supplying individual laborers has increased to more than 3,000.

These collective and individual economies are guided by state planning and subjected to the relevant state policies and rulings, and form an important component of as well as a necessary supplement to the reclamation area economy. These collective and individual economic units are mainly engaged in economic diversification, social services and small-scale processing of agricultural and animal products. Some of these activities take the form of independent management; others are integrated into contract with state farms and state pastures for cattle raising or for planting cash crops. Their forms of operation are many and varied, with wide adaptability.

In the past, the task of providing jobs for the sons and daughters of the workers was undertaken exclusively by the state. With the universal popularization of the system of production responsibility in various forms, the intensified enterprise reorganization, and organization of production according to a fixed number of workers and fixed quotas, such exclusive undertaking is no longer possible. Furthermore, the number of senior and junior secondary school graduates is continuing to increase. The emergence of collective and individual economies has opened a new avenue of job opportunities. Up to now, the collectively-owned enterprises have accommodated more than 27,200 sons and daughters of the workers, or 35.9 percent of the total number of job-awaiting youths. Reform of the economic structure with a single system of ownership has also provided favorable conditions for changing the system of a single form of business operation and for promoting the all-round development of economic diversification. Active development of collective economy in No 8510 Farm on the basis of local natural resources has not only provided job opportunities for 771 unemployed youths in the farm, but also enabled them to undertake more than

20 production projects which yielded a total output value of 650,000 yuan last year. The albumen powder fodder factory under the industrial company of No 93 Farm Administration Bureau has only 61 workers and staff members, but is capable of producing 2,260 tons of compound fodder each year with grass, bean cakes and chaff. Its product is well received by the consumers and is now sold outside the province. The collective and individual economic units engaged in commerce, food and drink service, or repairing and assembling are now filling the gaps left by state-run commerce.

These changes in the economic structure of reclamation areas deserve our attention. Wang Zhenyang [3769 2182 2254], party committee secretary and chief of the provincial General Farm Administration Bureau to the correspondent: "If all people in the reclamation areas are directing their efforts to state-run enterprises, the scope of their activities will become increasingly small, until finally they cocoon themselves like silkworms. There should be without exception a multi-level economy in all reclamation areas. We must pay simultaneous attention to state, collective and to a certain extent individual economies in order that there can be a broader scope for the development of the reclamation areas and greater vitality for the economy."

RESPONSIBILITY SYSTEM EFFECTIVE IN HEILONGJIANG COUNTRYSIDE

Harbin HEILONGJIANG RIBAO in Chinese 11 Apr 82 p 1

[Article by HEILONGJIANG RIBAO correspondent: "Responsibility System in the Province More Effective This Year--Provincial Rural Work Department Comments on Situation After Introduction of Responsibility System"]

[Text] Commenting on the situation in the countryside after the introduction of the responsibility system recently, the provincial rural work department was of the opinion that the enforcement of this system this year should be more effective than it was last year, and that the trend of its development is healthy. At present, the all-around improvement of this system should be continued so that it could provide a more powerful impetus to the smooth progress of spring farming and production throughout the year.

By now, more than 90 percent of all production teams in the provinces have adopted various forms of responsibility systems. Compared with last year, it has now the following salient features: 1) The number of production teams adopting various forms of output responsibility system has been greatly increased, and these production teams account for 75 percent of the total number of production teams, an increase of 40 percent over last year. The proportion of those adopting the system of short-term contracts has dropped from 50 percent to 25 percent. More than one-half of all production teams have adopted the system of linking output with individual labor. In the fairly highly mechanized wheat and bean producing areas and in some production brigades conducting experiments in mechanization, including the farm machinery teams, there has been great development in various forms of output responsibility. According to statistics in the three prefectures of Heihe, Hejiang and Nianjiang, 44.6 percent of all farm machinery teams have adopted the system of output responsibility. 2) The substance of the responsibility system is now more comprehensive. This year, all localities have drawn their lessons from last year's experiences and are able to handle the combination of unified control, specialized skill and contracting more rationally. Planting plans, machinery, trucks, horses, major production expenses, farmland construction and the distribution of products were brought under unified control as they should be. In the method of contracting, there should generally be specialized skill before responsibility. All specialized jobs, such as those relating to farm machinery, farm animals, fertilizer accumulation, forestry, animal husbandry, sideline production, fishery and industry, should be contracted to persons with specialized skill. In handling the relationships of interests among the state, the collective and the individuals, the production teams had some problems last year, such as quotas being set too low, the free disposal of products, and improper ways of reward and punishment. This year, measures have been taken for improvement in these respects. 3) The responsibility system is more complete. Formerly, people thought that certain tasks, such as animal raising, financial management, agrotechnology, irrigation from wells with motor-driven pumps, logistic support, enterprises run by communes and production brigades and so forth might create problems for the responsibility system. This year, the responsibility system has been duly improved to handle these tasks. The contract system between science and technology on the one hand and production on the other has been greatly developed, and joint undertakings have developed from single to multiple projects. The responsibility system for paddy rice technicians has been popularized throughout the province. In Suihua Prefecture, the number of production teams practicing the system of contracts between science-technology and production is now 17.5 times that of last year. 4) Attention has been paid to the popularization of the contract system. Up to now, more than 30,000 production teams throughout the province have signed some million contracts. In the prefectures of Nianjiang and Suihua, 80 percent of all production teams have signed various types of contracts which are now being systematically reviewed.

However, some urgent problems are waiting to be solved in various localities. 1) The responsibility system is not being enforced in certain communes and production brigades. At present, 40 percent of the production teams have not signed any contract. In some production teams, the cadres only talk about responsibility system and have so far taken no concrete action of any kind to hold the contractor responsible. Some of them have signed short-term contracts, but some of these contracts do not specify any quotas, and there is no system of inspection or control set up. 2) The substance of responsibility system in certain localities is not comprehensive enough. In some production teams, the substance of the responsibility system is neither complete nor elaborate; in others, the proportion of labor power to the number of persons is irrational in dividing responsible plots, because the principle of giving primary consideration to labor power is not followed. Some production teams are only concerned with the commune members, and the production quotas are set too low. Some job responsibility systems for cadres are too complex and rewards are excessive. Some communes and production brigades pay attention only to the system of responsibility for field production but not to the related responsibilities. There are also some production teams which sign contracts without going through the proper procedures. The contents of their contracts are vague, and unified control is nonexistent. 3) In a small number of communes and production brigades, the problems of disregarding mass wishes and imposing "arbitrary uniformity" still exist. In certain production teams, leadership is abandoned and people seem to be on a sit-down strike.

Now that spring farming is forthcoming, all these urgent problems must be solved. First, we must sign proper contracts. This is the key factor in enforcing and stabilizing the responsibility system. Those production teams which have not yet practiced this system should quickly do so through the signing of contracts; those production teams in which the responsibility system has not been finalized should finalize it through the signing of contracts; and those in which the system has already been finalized should also confirm it in the form of contracts. Second, we must carefully review the responsibility system. Before spring sowing, all localities should organize their cadres to visit the communes and production brigades for a general inspection on the enforcement of the responsibility system, with particular stress on its practical enforcement; on the coordination of unified control, specialized skill and contracting; on the correct handling of relationships of interests among the state, the collective and the individuals; and on the contents of signed contracts, in order that whatever is found missing can be made up and whatever problem brought to light can be promptly solved. These measures will further improve the responsibility and contract systems. Third, leadership must be strengthened in setting up the responsibility system, and even more so in its enforcement. Therefore, we must plan our work more actively and scientifically. After all, we must help the basic level cadres learn to organize production through the use of contracts, to manage the collective economy effectively, and to build a modern agricultural base for the all-around development of cash crops and economic diversification, with commercial grain as the main item.

BRIEFS

LIUZHUANG BRIGADE COMMENDED--On the eve of the party anniversary, the Xinxiang prefectural CCP Committee issued a notice commending the party branch of Liuzhuang Brigade in Xinxiang County, famous throughout the country, and 100 other progressive party branches and 296 outstanding party members. The common characteristics of these party branches and members are that they have seriously implemented the line, principles and policies laid down since the third plenary session, upheld the four basic principles, and scored outstanding successes in building socialist material and spiritual civilization. The prefectural CCP Committee calls on the grassroots party branches and party members throughout the prefecture to rapidly whip up an upsurge of comparing themselves with, learning from, catching up with and helping others. They should raise the emulation drive to a new level. [Text] [HK010533 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 30 Jun 82]

BRIEFS

COTTON PRODUCTION CONFERENCE--The Hubei Provincial Conference on cotton production which was recently held in Zhijiang County stressed that the key to striving for a bumper cotton harvest this year lies in strengthening middle- and final-stage field management. The conference pointed out that July, August and September are the decisive period for the growth of cotton. The conference demanded that all places do well in tending cotton at the middle and final stages. Field management includes application of manure on cotton, plant protection, combating natural disasters, making unified arrangements and taking grain and cotton production into consideration. BRIEFS

PREFECTURAL SUMMER CROPS--Huaiyin Prefecture, Jiangsu, reaped good harvests from its 6.9 million mu of wheat, barley and naked barley this year, with the total output increasing by some 600 million jin compared with 1981. [OW150035 Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 26 Jun 82]

HYBRID RICE--Jiangsu Province has achieved results in popularizing a hybrid rice. During the last 3 years, the province has planted about 10 million mu to this hybrid rice each year. Last year the crop gave an average yield of more than 800 jin per mu, or some 100 jin above the output of the ordinary variety. This means an increase of some 1 billion jin in the province's total rice production. [Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 4 Jun 82 OW]

BRIEFS

FLOODED COUNTY--By 26 June, the masses in Lean County, Jiangxi Province, saved 60,000 mu of various crops from the flood and repaired more than 600 water conservancy projects of various sizes. In addition, more than 400,000 jin of fine late rice seeds have been obtained by the county. The masses in the county will expand diversified farming operation to make up for the losses in grain crops. The county's financial department has appropriated 160,000 yuan for the repair of water conservancy facilities and bridges. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 28 Jun 82 OW]

BRIEFS

WHEAT OUTPUT--Bayannur League's 1.85 million mu of wheat is growing well in 1982. This league has expanded its wheat farming acreage by 125,000 mu. The output is expected to increase 10 percent. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 6 Jul 82 SK]

GRASSLAND SHELTERBELTS--The Xilin Gol League Forestry Bureau in Nei Monggol autonomous region succeeded in the experiment of planting trees in large areas of dry grasslands without any irrigation facilities. The bureau has built in Xianghua Banner 1,821 mu of grassland shelterbelts on 3 different types of soil. Elms, Chinese wolfberry and poplar trees were planted. Their survival rate was 75, 85 and 95 percent, respectively. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 1 Jul 82 SK]

HERDSMEN'S INCOME--According to a survey of 51 herdsmen households, the average per capita income of herdsmen in 1981 was 315 yuan in Ju Ud League, Nei Monggol, an increase of 74 yuan over 1980. The income of herdsmen from the collective was 151 yuan per capita on the average, an increase of 48 yuan over 1980. The average income from household sideline occupations for each herdsman was 187 yuan, an increase of 34 percent. The average per capita expenditures paid in cash was 250 yuan. WORK CONFERENCE DISCUSSES URBAN WATER PROBLEMS

Jinan DAZHONG RIBAO in Chinese 1 May 82 p 1

[Article: "Devote Attention to Urban Water Use in the Same Way as to Energy. Provincial Government Convenes Work Conference on Urban Water Utilization Throughout the Province. Demands Adherence to a Policy of Simultaneous Development of Resources and Conservation of Flow and Vigorous Solution of Problems in Urban Water Utilization"]

[Text] Recently the Provincial People's Government convened a work conference on urban water utilization throughout the province, which demanded that each municipality adhere to a policy of simultaneous emphasis on development of resources and conservation of flow, giving vigorous attention to urban water use in the same way as for energy, in order to make a contribution in promoting development of the national economy.

Comrades attending the conference conscientiously reviewed development of the province's urban water utilities and analyzed the current situation in supplying water. They acknowledged that the province's urban water supply utilities have grown rapidly and that capabilities to supply water have greatly increased, but that they are a very long way from being able to meet needs for the building of production and improving the people's standards of living. At the present time, 10 of the province's cities are daily 1 million tons of water short. Inadequate urban water supply has become a problem urgently requiring solution.

The conference recognized serious waste in the use of water as one of the main reasons for the water shortage in many cities. It asked that the entire party in all cities act, and that all the people mobilize to bring about a rapid upsurge in the conservation of water. The key in water conservation work lies in conservation of industrial water, particularly water consumption by the biggest industrial consumers. Industrial use of water accounts for more than 70 percent of urban water use, and water use by large industrial consumers accounts, in turn, for more than 70 percent of industrial water use. To take hold of conservation in the use of water by large industrial consumers is tantamount to leading a "bull by the nose." All enterprises are to treat water conservation in the same way as energy conservation, make it a part of technical restructuring plans, and vigorously promote new technology and new techniques for the conservation of water. They should go all out in the recycling of cooling water, in the recovery of waste water, in using the same water to do different things, and in combining the use of water to effect water savings. They should strive to increase the multiple utilization rate of water. All cities are to make improvements in the industrial multiple utilization rate for water a major method for solving urban water difficulties, so that within 2 or 3 years the multiple utilization rate will reach the more than 40 percent standard set by the state. Conservation of the use of water in daily life should also be diligently tackled and waste prevented. The "flat rate system" and "drinking water out of a large common pot" for water used in daily life has to be changed within a short period of time and meters installed in every household to register consumption for collection of fees.

The conference emphasized the need, while ferociously tackling water conservation, to arouse the enthusiasm of all quarters to devote major efforts to building new water sources and to expand capabilities to supply water as fundamental ways to solve urban water problems. They asked that all levels of leadership and units concerned make a decision to allocate funds for the building of new water sources in preference to the building of several plants. They should gain a clear understanding of ground water resources with all possible speed, draw up plans for building new water sources, and carry them out one by one over a period of time in order of importance and urgency. As regards funds for the building of new water sources, the initiative of the central government, local governments and enterprises should be brought into play in a cooperative effort to solve the problem.

The conference asked all levels of government to place on their important daily agendas solution of urban water problems, and to conduct regular study, assignment of resources, and inspection. Leaders responsible for industrial production should both look after the completion of production plans and economic quotas, and give attention to planned use of water and conservation in the use of water. All levels of design commissions, economic commissions, construction commissions, urban construction and water conservancy units should closely coordinate and work in concert to solve urban water problems.

EDITORIAL URGES EQUITABLE USE OF URBAN WATER RESOURCES

Jinan DAZHONG RIBAO in Chinese 1 May 82 p 1

[Editorial: "Equitable Development and Use of Urban Water Resources"]

[Text] Water resources, like energy resources, are a part of the basic structure of the national economy, and are the principal factor restricting urban development. In a certain sense, water resources are even more important than energy resources. Equitable development and use of urban water resources is a major matter bearing on the national economy and the people's livelihood, and a strategic issue that should arouse a high degree of serious attention.

Shandong Province has very great accomplishments in the development and use of urban water resources. However, as a result of the past influence of "leftist" ideology and the longterm lack of centralized planning and management, development and use of water resources has been in a virtual state of anarchy, which has seriously damaged the regenerative capacity and balance of water resources, bringing about a situation of extreme shortage in urban water utilization. Change of this situation will require that efforts be devoted to equitable development and use of urban water resources.

Equitable development and use of urban water resources requires, first of all, increased awareness of the importance of water resources. Formerly it was generally believed that water resources were relatively abundant when, in fact, this was not so. Shandong Province is a water-short area. Current needs for water for industrial and agricultural production and for daily urban life are very greatly in excess of the total volume of useable water from above ground, underground, and from the Huang He. Given the present state of development of science and technology, nothing can take the place of water. Man has lived through times when there was no petroleum, electricity was not used, and there was a shortage of coal, but he has never lived for a single day in a world without water. How to develop and use such precious and limited water resources not only bears on urban construction and a secure life for the people, but also bears directly on development of the entire national economy. Hence it is necessary to highly treasure and equitably develop and fully use it.

Equitable development and use of urban water resources requires change in the former state of anarchy and the practice of centralized planning and centralized management. For a long time Shandong Province's urban water resources have not been centrally managed. Every unit using water has proceeded from its own needs, deciding for itself where and how it would tap water. In some cases, enterprises right next door to each other sank separate wells in competition for water, causing too much to be extracted and a large drop in the ground water table. Practice has shown that urban water resources are parts of a totality and that reckless and unbridled tapping of them must inevitably seriously damage the regenerative capabilities and balance of water resources. It should be clearly pointed out that ground water resources like soil, forests, and ore reserves, are not the property of a single unit but rather the property of the country. Thus they must come under centralized state management. This was not done in the past because of the influence of "leftist" ideology and mistakes we made in work. Unless urban water resources are brought under centralized management and serious attention given to overall planning and scientific tapping and use, continued destruction of water resources will be a great mistake that will adversely affect generations of posterity.

In urban development plans, equitable development and use of urban water resources must adhere to the principle of doing only what the quantity of available water permits. In urban contruction, water resources are one of our points of departure in considering problems. No matter whether planning, running industries or operating other enterprises, no matter what we do, this problem has to be considered. In undertaking a project, it is necessary to find out, first of all, whether water is available and how much of it, after which it can be decided whether or not to undertake the project and at what scale. If an industrial plant is built blindly without regard for water resources, the completed plant will be unable to go into operation. Not only will no benefit result, but the country's manpower, wealth, and material resources will have been wasted. We cannot perpetrate any more such stupidities. Every city should diligently study the lessons of experience in this regard and really proceed from improvement of economic benefits to handle matters in accordance with objective laws. In future until new water resources have been found to solve the problems of water-short cities, there should be no further construction of industrial projects that consume large quantities of water.

Serious waste of water is one of the major reasons why many cities are short of water. Conservation of the use of water is a major aspect of the equitable development and use of urban water resources, and it is also a way, requiring little investment, that is readily workable, and that shows results quickly for ameliorating and solving the current urban water shortage. We must widely publicize in every industrial and mining enterprise and among the people throughout the province, the importance of conservation in the use of water to establish a concept of water resources as an extremely precious thing. Conservation of water use should be given attention in the same way as conservation of coal, electricity, and petroleum, and particular attention should go to conservation by big industrial consumers of water, with efforts made to increase industry's multiple utilization rate for water. Effective work must be done in keeping clear water and waste water separate, in recycling water for use, and in combined use of water using the same water for many things. Where conditions permit, full use should be made of sea water and mineshaft water. Waste water, a potential energy resource, should be fully recovered for use. Economic methods must be used to strengthen management over the use of water so that the quantity of water used becomes closely linked to the economic welfare of the user. Conservation of water should be made a part of enterprise technical restructuring and energy conservation plans, and used as a major indicator in assessing enterprise management levels and administrative effectiveness. At the present time, the important value and position of water resources as well as the equitable development and use of urban water resources are becoming more and more a part of people's perceptions. Let us act positively and strive together to do an effective job in the equitable development and use of urban water resources to make a new contribution to building the four modernizations.

WHEAT CARE POINTERS GIVEN ON EVE OF HARVEST

Jinan DAZHONG RIBAO in Chinese 1 May 82 p 1

[Article: "Make Further Efforts To Combat Drought To Protect the Wheat"]

[Text] A little more than a month still remains until the wheat is harvested, and this is a decisive period of time. This is the key period when the grain weight of the wheat will be decided, and it is also the period when various natural disasters are likely to occur. How well the fields are cared for will play a decisive role in whether the wheat harvest is a fat or a lean one. Past practice has shown that when good care is given during the late season, the per 1000 grain weight increases and output goes up. Conversely, output is seriously hurt. Consequently, we must assiduously summarize the lessons of experience in this regard and take greater action to do a good and intensive job of caring for the wheat during the late period, with no relaxation of care until a bumper harvest is in hand.

Effective late stage wheat care entails focusing on its great needs for water and fertilizer as a result of the current serious drought situation, and as a result of the large consumption of nutrients during its late growth stage. This requires earnest attention to watering to combat drought and to sensible top dressings of fertilizer to assure necessities for wheat growth. It also requires prompt hoeing to eliminate weeds and to loosen the soil to conserve soil moisture. As temperatures rise, outbreaks of wheat aphids, wheat rust, powdery mildew, and such diseases and insect pests will occur one after another, so pesticides and pesticide apparatus should be made ready and forecasting and reporting work should be intensified so that prompt prevention and control can be done upon discovery, and the diseases and insect pests wiped out when they first break out.

Hot dry winds are the major disaster to befall wheat in Shandong Province during the late season. They do much damage to output and require that watering for wheat ripening be done, or that petroleum growth promoters be sprayed, or that potassium dihydrogen phosphate be applied for active prevention to reduce damage insofar as possible. Additionally, in fields where individual plants are too numerous, making ventilation and light penetration poor and the stalks and stems spindly and weak, action must be taken to prevent lodging to guard against decreased yields.

BRIEFS

AUTUMN CROPS--Having completed the sowing of over 50 million mu of autumn crops, cadres and the masses in Shandong Province's rural areas now shift their attention to field management and autumn farming. By the end of June, the province hoed 50 million mu of farmland, topdressed 37 million mu of fields and controlled insect pests on 28 million mu of fields. [SK052255 Jinan Shandong Provincial Service in Mandarin 2300 GMT 4 Jul 82]

WHEAT HARVESTING--Thanks to dry and hot winds and the fainfall in late May, the wheat crop throughout Shandong Province has ripened earlier than usual. The broad masses of rural cadres and the people are plunging into wheat harvesting. As of 5 June, the province has harvested over 17 million mu of the wheat crop. Heze and Linyi Prefectures and Zaozhuang Municipality have fulfilled their wheat harvesting task by 60-70 percent. [SK070637 Jin Shandong Provincial Service in Mandarin 2300 GMT 5 Jun 82]

WHEATFIELDS--Shandong Province has achieved good results in interplanting summer-sown crops with wheat on wheatfields. Some 20 million mu of summer-sown crops have been interplanted. Some 19 million mu were devoted to corn. This has created a favorable condition for a good autumn harvest. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 15 Jun 82 SK]

AUTUMN HARVEST MEETING--The Shandong Provincial CCP Committee recently held an emergency meeting urging efforts to pay close attention to summer planting and field management to enable a good autumn harvest to compensate for a decreased summer harvest. The provincial CCP Committee held that it is possible to overcome the decreased summer harvest with a good autumn harvest because grain output is two-thirds of the annual grain output, and spring-sown crops totaled 46.8 million mu in the province, 3 million mu more than in 1981, and seedling growth was good. The meeting called for efforts to guarantee grain areas while stabilizing the acreage of cotton, peanuts and tobacco; to plant more high-yield crops such as sweet potatoes resistant to drought and infertile soil; and to strengthen and improve responsibility system. [SK171009 Jinan Shandong Provincial Service in Mandarin 2300 GMT 15 Jun 82]

REMEDIAL PRODUCTION MEASURES--The CCP Committee and administrative office of Weifang Prefecture, Shandong Province, sponsored a wired broadcasting rally on 5 June, urging the people throughout the prefecture to grasp well summer harvesting and sowing in a timely manner and vigorously engage in summer farming in an effort to achieve a better autumn harvest to make up the loss of wheat output caused by the serious drought. To successfully fulfill the annual production plan, the rally urged counties under the prefecture to do a good job in strengthening the field management of corn crops and planting sweet potatoes. Over 1.4 million mu farmland from which wheat has been reaped in the prefecture should be planted with sweet potatoes on a crash basis. Efforts should be made to ensure a full stand of potato seedlings. Meanwhile, the rally urged localities to adopt every possible means to engage in the production of a diversified economy to increase their annual income as much as possible. ATTENTION DRAWN TO EROSION PROBLEMS IN CHANG JIANG BASIN

Shanghai WEN HUI BAO in Chinese 9 May 82 p 1

[Article: "Chang Jiang Basin Erosion Serious, Comprehensive On-the-Ground Investigation at 19 Counties in 10 Provinces and Regions Reveals. Experts Believe This Has Been Brought by Clearing of Steep Slopes and Severe Destruction of Ground Cover"]

[Text] Since 1958 erosion in the Chang Jiang basin has become increasingly serious, and the trend toward deterioration remains unhalted. Experts concerned from the Chang Jiang Basin Planning Office, the Chinese Academy of Sciences, and the Beijing Forestry Academy came to this conclusion following on-the-spot investigations at 19 key counties where erosion has taken place in the Chang Jiang River basin.

Beginning last October the Chang Jiang Basin Planning Office was entrusted by the National Agricultural Commission to organize more than 100 water and soil conservationists from provinces and regions concerned to take part in an on-the-spot investigation of key erosion areas in the Chang Jiang basin. This investigation lasted for more than 3 months. This was the first comprehensive scientific investigation of soil and water resources in the Chang Jiang basin that China has ever undertaken.

Results of the on-the-spot investigation showed serious erosion to have taken place in the basins of some of the tributaries of the Chang Jiang. Both banks of the Wu Jiang, a tributary of the Chang Jiang that flows through Guizhou Province, used to be densely covered with large, lush forests. Now, however, as a result of reckless cutting and denudation, many mountainlands have been turned into slabstone slopes where not even a blade of grass grows. Erosion in Sichuan Province is rather astounding. Last year 540 million tons of silt from this province flowed into the Chang Jiang. This is almost the equivalent of 10 million mu of cultivated land to a depth of more than 10 centimeters having been washed away. As a result of their on-site investigation of 19 counties in 10 provinces and regions, the experts discovered that the soil layer in these places was in process of gradually becoming infertile, and that some soil has already lost its value for use in agriculture.

Some of the experts who participated in the scientific on-the-spot investigation believe the main reasons for the increasingly serious erosion of the Chang Jiang basin lie in the clearing of steep slopes and severe destruction of ground cover. Because of mistakes made in our work and unplanned population growth in some places, tremendous pressures have been exerted on local agricultural production. This has led, in turn, to reckless cutting and denudation of forests and blind clearing of land in order to satisfy increasing requirements for the necessities of life such as grain rations and fuel.

The experts believe that comprehensive action must be taken to bring the problem of erosion in the Chang Jiang basin under control. In the Chang Jiang basin, temperatures are moderate, rainfall copious, and the restorative and regenerative powers of trees, bushes and grasses are rather strong. If strict action is taken to close off mountains to propagate forests, within 2 or 3 years time the vegetation cover rate for the Chang Jiang basin will very greatly increase.

AGRICULTURAL DEVELOPMENT ATTRIBUTED TO RESPONSIBILITY SYSTEM

Taiyuan SHANXI RIBAO in Chinese 12 Apr 82 p 1

[Article by SHANXI RIBAO correspondent: "Excellent Situation of Agricultural Development in Our Province From Introduction of Responsibility System in Various Forms"]

[Text] The responsibility system in various forms has been basically adopted in our countryside, and major changes are now things of the past. The various forms of responsibility system are in the following proportions: Out of more than 126,000 accounting units in the province, 1.9 percent of them have adopted the system of paying remunerations according to short-term contracts; 5.4 percent, the system of remunerations according to the output of special farm work done; 11 percent, the system of unified management and paying remunerations according to output from individual labor; 1.5 percent, the system of unified management and paying remunerations according to the result of production groups; 9 percent, the system of unified management and fixing production quotas on the basis of households; 69 percent, the system of unified management and allotting work to individual households; 1.9 percent, the system of private plots and responsibility plots; and 0.3 percent, the other forms.

Last December, before the all-round improvement of the responsibility system, it was tentatively arranged that 36 percent of these accounting units should adopt the system of fixing production quotas on the basis of households or allotting work to individual households. This year, as we can see, these units have increased to 78 percent instead of being decreased. It shows that since the people are aware of the actual conditions, such a high proportion is practical and conforms to the present level of productive forces in most rural areas. It is not true that uniformity has been arbitrarily imposed on the responsibility system.

Implementation of the responsibility system this year has brought about an excellent situation in the development of the countryside. Fixing production quotas on the basis of households and allotting work to individual households are important components of the socialist rural economy, and this fact has been implicitly acknowledged by the cadres and commune members in the countryside. The misunderstanding on the part of some peasants who mistook allotting work to individuals for dividing up collective land for individual farming and so forth has been made clear, and they no longer fear that the responsibility system may soon be changed. Many concrete problems, such as the irrational distribution of plots to individuals, have been gradually solved. The people are now feeling at ease, and their enthusiasm, having been aroused, is being transformed into even greater material forces. More and more commune members have quietly bought fine strains, chemical fertilizers, machinery and other means of production by doubling or redoubling their investments in this year's expanded reproduction. "Greatly increased output" and "above-quota output" have become the common topics of conversation among the cadres and commune members. The cadres at the county, commune and production brigade levels have become more ideologically enlightened, and the conflicting ideas which existed among them last year have disappeared. The "leftist" ideas have been basically overcome. The party committees at various levels are now more experienced in organizing their leadership over the introduction of the responsibility system. Thus there is now a strong impetus to the development of an excellent situation in agricultural production.

Of course, there is still a great deal of work to be done in perfecting the responsibility system, and it is necessary for leaders at various localities to go deep among the basic level units for investigation and study in order to uncover problems and solve problems.

BRIEFS

SPRING SOWING IN SHANXI--State plans for spring sowing in our province have been completed. According to statistics, the acreage of grain crops for spring sowing this year is 33,260,000 mu, an increase of 470,000 mu over last year; that of cotton, 3,699,000 mu, some 99,000 mu over the state plan; that of oil-bearing plants, 3,594,000 mu, an increase of 54,000 mu over last year; that of beetroots, 295,000 mu, an increase of 15,000 mu over the state plan; and that of tobacco, 100,000 mu, of which 115,000 mu has been initially completed. With a clear understanding of the principle that "planned economy should prevail and the regulation by the market can only be supplementary," the leaders at all levels and the broad masses have regarded arrangement of the crop pattern as a strategic task and adapted their measures to local conditions so as to bring the local strong points into play. That is why the state plans for spring sowing this year have been fairly well completed. [Text] [Taiyuan SHANXI RIBAO in Chinese 17 Apr 82 p 1] 9411

CSO: 4007/419

EMPHASIS PLACED ON PADDY RICE FOR GOOD GRAIN HARVEST

Chengdu SICHUAN RIBAO in Chinese 10 Apr 82 p 2

[Article by Cui Mingxin [1508 2494 2450]: "Pay Main Attention to Paddy Rice in Striving for Good Grain Harvest This Year"]

[Text] Paddy rice is the main spring grain crop in our province. Its acreage accounts for approximately one-third of the total grain acreage, and its output accounts for approximately one-half of the total grain output. It therefore occupies an important place in grain production. Giving full play to the strong points of paddy rice and accelerating the development of its production will certainly be an effective way for the province to maintain a steady increase in grain production.

First, we should carefully arrange the crop pattern and, if conditions permit, gradually expand its acreage. As shown by many years' experience, it would be practical to have a crop pattern with middle rice in the dominant position, if we take the situation of the whole province into account. Such a pattern will enable paddy rice to grow in the most favorable season and yield a bumper harvest. In eastern and southern Sichuan, where the weather is warm and sunlight and water resources are plentiful, it would be desirable to develop double crops of rice as a means of fully utilizing natural resources to increase rice output. The present distribution of paddy rice fields is basically rational and should remain unchanged in the near future. In recent years, some localities have made great efforts to raise the per-unit output and at the same time actively improved their irrigation facilities, expanded their farmland and increased their paddy rice acreage with good results in increased output. Santai County has done a great deal of work in water conservation since 1980, and in 1977, took strong measures to transform land into paddy fields. It has not only created the necessary conditions for raising the per-unit output but also expanded the paddy rice acreage every year. Thus in 5 years, more than 60,000 mu of dry land was transformed into paddy fields. In 1980, compared with 1976, the total paddy rice output increased by 61.2 percent, and its per-unit output reached 967 jin, an increase of 409 jin. The total grain output was increased by 46.9 percent, with an average progressive increase of 10.1 percent each year. Therefore, the planned and systematic expansion of paddy rice acreage will enable the province to make better use of our natural resources and accelerate the development of paddy rice production.

Second, we should actively popularize the use of hybrid rice and regular fine strains and take advantage of the latter's strong points. Every leap in the per-unit output of paddy rice in our province began with the use of some new fine strains. In the 1970's, the experiment in ternary bybrid was a success which marked a breakthrough in paddy rice production and raised the per-mu output to more than 1,000 jin in large areas. In 1981, more than 13 million mu was planted with bybrid rice in the province, and the average per-mu yield reached 901 jin. The use of hybrid rice alone enabled the province to raise its cereal output by more than 700 million jin. Of course, the scope for the use of hybrid rice is limited, because its use calls for suitable weather, water and fertilizer conditions, and a proper arrangement of crop order. Attention should be paid to the simultaneous popularization of both fine strains and good methods. In eastern and southern Sichuan, where the weather is hot and dry, it is particularly necessary that hybrid rice fields be well supplied with water, and the planting should be carried out with methods suitable to local conditions.

Regular rice does not have such a high per-unit output as that of hybrid rice, but the scope of its use is generally broader, and its acreage can be wider. In future, the proportion of regular rice to be planted should be fairly high. Therefore, we should popularize both hybrid rice and the regular fine strains. The old strains which contain impurities and have degenerated should be replaced by new high-yield strains in the course of popularization.

Third, we should greatly improve our planting techniques with particular attention to the cultivation of seedlings. Sturdy seedlings is an important condition for the increase of paddy rice output, and the remarkable rise in the per-unit output of paddy rice in our province in recent years was closely related to the improvement of our techniques in cultivating sturdy seedlings. If we want to further raise the per-unit output of paddy rice, we should further improve our planting techniques with particular attention to the cultivation of seedlings. Practice has shown that the method of nurturing seedlings in hothouses and then planting single stems in seedling fields for better tillering has many advantages, such as the ability to withstand unfavorable weather in the early spring and the higher speed of growing; early tillering and high elasticity of seedling age, with better quality and higher survival rate; the ability to avoid the effects of high temperature in the dry summer season and low temperature at a later stage, more ears, earlier maturity and higher yield; the advantage of leaving selected seedlings in seedling beds, which will help raise paddy rice output; and better utilization of labor in developing the tradition of intensive farming. This method of seedling cultivation should be popularized not only for hybrid rice, but also for regular middle rice planted in other types of fields. For early rice, the method of cultivating seedlings in hothouses or under plastic sheets should be widely used in order to keep the seedlings from rotting and to hasten the growth of paddy rice. This will also enable us to plant the late rice earlier and to raise its output. At the same time, attention should be paid to the scientific use of fertilizers, to rational close planting, and to the prevention of insect pests.

Fourth, we should strive to raise the output in the medium and low output areas so as to maintain a well balanced increase. The seven prefectures and municipalities in eastern and southern Sichuan are important paddy rice producing areas. Their rice acreage accounts for more than one-half of the total provincial acreage, and in the past several years, the restoration and development of paddy rice production were quite rapid. In 1981, the average per-mu output from more than 23 million mu in these seven prefectures and municipalities increased by 51 jin, and the total net increase was more than 1.2 billion jin. The rate of increase was more than 9 percent. At present the paddy rice output in most counties is at the medium or low level, and there is good potential for further increase. Although the river valleys are dry and hot, and the mountainous areas are cold with drizzles in eastern and southern Sichuan, there is always warm weather with abundant sunlight, water and other natural resources in most places. As long as the crop pattern is rational and proper methods are used in planting, it is entirely possible for the output to be raised by a wide margin. If the per-unit rice output in eastern and southern Sichuan can be raised to the average provincial level, the cereal output will be increased by more than 1.9 billion jin.

There are more than 6 million mu of rice fields in the 39 counties in the mountainous areas surrounding the plain in our province. The paddy rice output in most of these counties is still low. The natural climate and the conditions of production in these places are rather poor; however, as long as we take the realities in mountainous areas into account, follow the natural law, and combine traditional farming with agrotechnology, we can still obtain high yields. In the past, the seven mountainous counties in Ya'an Prefecture had about the same per-unit paddy rice output as that of the other mountainous counties. In recent years, these counties constantly explored the methods of raising paddy rice output and summed up their experiences in the light of the characteristics of mountainous areas, such as low temperature and scarcity of sunlight. After certain experiments, they actively popularized the use of hybrid rice and duly improved the methods of planting, with the result that paddy rice output was raised by a wide margin. In 1981, the average per-mu paddy rice output in these seven counties was 785 jin, or 84 jin higher than the provincial average. Among them, Hanyuan, Tianquan and Lushan counties had per-mu outputs of more than 800 jin, while Shimian County's was above 1,000 jin.

Paddy rice production in our province has entered a new stage of development, and the prospects are very bright. As long as we provide more active leadership, rely on correct policies and science, and take various realistic key measures, a sustained increase in the output of paddy rice is entirely possible.

MEASURES TO FIGHT DROUGHT SURVEYED

Tianjin TIANJIN RIBAO in Chinese 8 May 82 p 1

[Article: "The Fight Against Drought--Focus of All Rural Work"]

[Text] A spring farming and production campaign focusing on the fight against drought to assure vegetables, to assure the summer harvest, and to assure spring sowing is now being urgently conducted in the suburbs of Tianjin and in the rural villages of the county. Throughout the municipality's rural villages, the broad masses of cadres and people are sinking wells along the edges of fields, digging ditches, leveling the land, and diverting water. Between the lunar new year and the present time, 868 new wells have been sunk, 888 have been equipped, and 1,033 decrepit wells have been put back into production. More than 400 spray irrigation machines have gone into operation, and more than 120,000 meters of ditches have been repaired to prevent leaks. In addition, more than 11,000 pump wells have gone into operation and temporary pump sites have been set up at more than 2,000 sites. As a result, despite the serious drought situation, 1.14 million mu of wheatfields in the municipality's rural villages have been watered, 890,000 mu of unplanted fields have received a spring watering, and 1.23 million mu of open field crops have been sown.

As a result of 3 consecutive years of serious drought, the municipality's difficulties in agricultural production have become increasingly great. Right now there is virtually no water available for use above ground in rural villages throughout the municipality, and the ground water table has dropped everywhere. Volume of water from pump wells has greatly decreased, and more than 6,000 pump wells either are no longer able to produce water or produce only half the full rate. In addition, the high temperatures and strong winds since the lunar new year have caused a great amount of evaporation and loss of soil moisture. The amount of moisture deficient soil increases daily. The increasing drought situation seriously threatens both normal growth of crops to be harvested during the summer and uninterrupted spring sowing. Unless a soaking rain soon falls, harvest of 700,000 mu of the municipality's 2.2 million mu of summer grain crops cannot be assured. Of the 4 million mu to be sown during the spring, 1.8 million mu will not be sown on time, and because of the loss of soil moisture in the open fields that have already been sown, a full stand of crops cannot be readily assured. Therefore, an urgent task now facing the broad masses of cadres and people in the rural villages of Tianjin Municipality is to fight effectively the fight for spring farming and production centering on the fight against drought to assure vegetables, to assure the summer harvest, and to assure spring planting.

Beginning now, all rural work must center around and be subordinate to this focus on the fight against drought.

First it is necessary to inculcate a mentality of a fight against great drought and great disaster to win a bumper harvest, to guard against and overcome feelings of pessimism and fear of difficulties on the part of some cadres and a situation of letting matters take their course. While fully calculating difficulties, we must be aware of the advantageous conditions for victory over drought: The programs and policies that have ensued from the Third Plenary Session [of the 11th Party Central Committee] have sunk deeply into people's minds, and implementation of agricultural production systems of responsibility, in particular, have aroused the enthusiasm of the broad masses of cadres and people. The degree of farm mechanization in Tianjin Municipality is fairly high; water conservancy facilities are fairly complete; and material conditions for fighting against drought are also good. In the course of several years of struggle against drought, leaders at all levels and the broad masses have accumulated experiences in triumph over disaster to win bumper harvests for the year as a whole, with the summer harvest supplementing the autumn harvest, and the autumn harvest supplementing the summer harvest, etc. We must make full use of these advantageous conditions to actively overcome disadvantageous factors, to strengthen our confidence, and to do an effective job in "one combat and three assurances."

Second is the need to genuinely strengthen leadership of work to combat drought. This is crucial to winning victory in the struggle against drought. Leadership cadres at all levels are to devote their main energies to the struggle against drought. Ranking prefecture and county leaders, the infirm and those carrying out daily duties excepted, are to go down into the frontlines of the fight against drought to assign individual work tasks, to fix responsibilities, and to do everything possible. For communes and brigades in which the drought situation is serious, difficulties numerous, and production potential fairly great, particular attention should go to the transfer of competent cadres who can help solve conceptual problems and actual problems in fighting drought. In addition, it is necessary to stabilize and perfect production responsibility systems, giving attention to this as a major action in the fight against drought.

Third is the need to arouse the masses and take a firm grip on implementation of measures to fight drought. Right now the above ground water situation is utterly hopeless, so we must arouse the masses to vigorous tapping of ground water resources. Practice in many communes and brigades has shown that large-scale sinking of guozhui [6938 6923] wells, intube [2252 4619] wells, yaba [1090 2116] wells, and dug wells, and the digging down into rivers or deepening of ditches are all effective means of opening up water sources and launching struggle against drought. Additionally, attention has to be directed to the renovation, equipping, and maintenance of existing pump wells to increase the volume of water produced and increase benefits from individual wells. Wuqing County installed mechanical pumps, changed pump diameters, tightly sealed the pipe going down inside the mouth of wells, and renovated equipment to increase water lift, 497 wells thereby providing benefits to the full. This merits emulation. For those communes and brigades having requisite conditions, installation of some spray irrigation equipment should also be urged as well as the installation and repair of ditches to prevent leaks. In short, the masses should be fully aroused and relied upon, and every available means used to tap ground water sources.

Only slightly more than a month remains until summer harvest, and the time for spring sowing is also extremely pressing. Opportunities cannot be lost and the time will not return again. We must be sure to grasp firmly the opportune time, and take firm hold of wheatfield care and spring sowing. Places having water resources should give priority to the watering of wheat; 1 more mu watered makes 1 mu more. Additionally, much effort should go to spring sowing and interplanting to lay a good foundation for the autumn crop to supplement the summer crop. All vigorous actions should be taken to plant whatever ground can be planted, and when planting genuinely cannot be done, preparations should be made to change from spring to summer planting.

Industrial, transportation, financial and trade units are to vigorously support the fight against drought. They must do urgently whatever is urgently required to fight drought, supply whatever is needed to fight drought, and increase work efficiency, contributing their strength to fighting disaster to win a bumper harvest.

ZHEJIANG

SHAOXING MUNICIPALITY GRAIN PRODUCTION INCREASE URGED

Hangzhou ZHEJIANG RIBAO in Chinese 3 Apr 82 pp 1, 3

[Article: "Establishing Measures To Emphasize Agriculture in Many Aspects, Shaoxing City's Communes and Brigades Encourage Farmers To Increase Output of Food Grains"]

[Text] Many communes and brigades in the farm villages of Shaoxing Municipality have implemented measures to emphasize agriculture in many aspects and have realized visible results. These measures to emphasize agriculture were carried out, starting from last year, to stabilize the foundation of agriculture and to guarantee stable increases in food grains production.

As sideline production of the communes and brigades develops, the labor force in the farm villages in Shaoxing City has continued to leave agriculture. Commune members engaged in farming must complete the tasks of unified procurement and assigned procurement of agricultural and sideline products for the state, and they must also solve the problems of providing food and firewood for industrial and sideline workers, who constitute 52 percent of the total labor force of the farm villages in the whole city. The working conditions, the economic gain, the welfare and salaries of industrial and sideline workers are generally better than those of commune members engaged in farming. This situation had seriously affected the enthusiasm of some cadres and farmers to increase the output of food grains. People wanted to work in the factories and leave the locality. The leading force on the frontline of agriculture and the labor force needed could not be guaranteed. To stabilize the foundation of agriculture and guarantee increased growth in food grains production, many communes and brigades in the farm villages in Shaoxing City started out from the actual situation and implemented a series of measures and policies to encourage farmers to increase the output of food grains at the beginning of 1981.

While establishing the production responsibility system for each profession, the communes and brigades in Shaoxing City insisted on taking the farming team as the basic unit to balance the basic salary and the ratio of awards in other professions. To enable the commune members engaged in farming to receive generally the same salary for an equal amount of work as in other professions, and to keep the salary of the farming team not lower than that in other professions, many communes and brigades paid widespread attention to grasping the following four points in establishing the goals of the responsibility system and in accounting: One was that the goals of the responsibility system in agriculture provided greater leeway. The goals of the "knowing early" plans and the goals of the responsibility system were not established too far apart so that agricultural output could surpass the levels of the past. The second was that the basic salaries determined at the beginning of the year by each profession and the estimated number of awards were both balanced on the basis of agriculture. The third was that the many kinds of overtime pay and subsidies of commune and brigade enterprises were controlled to prevent commune members engaged in industrial work receiving higher actual salaries than commune members engaged in agriculture. The fourth was that because agricultural production was limited by climatic conditions and because business of some enterprises was influenced by market factors, some situations could not be foreseen. To avoid large differences in salary among the professions, the method of "limiting awards, using surplus income to make up for deficiencies" was implemented by the enterprises. In this way, commune members engaged in agriculture willingly engaged in agricultural work and their enthusiasm was very high.

In the use of profits submitted by the enterprises to the higher authorities, a part was used by the enterprises to expand reproduction, another part or most was combined with the total output of food grains, revenue from diversification and important links to increase output, and the profits were given to the brigades. In this way, one act produced two benefits. Commune members engaged in agriculture benefited from the profits given them by the enterprises, and food grains production was stimulated. Jiefang Commune allocated 70,000 yuan from the profits submitted by the commune enterprises to the higher authorities and gave the money to the production team for use in connection with total output of food grains, for use to establish links to increase yield, livestock production, and planned parenthood. The concrete method of allocating the funds was as follows: An amount of 33,290 yuan was given to increase total output of food grains. For each 100 jin of food grains produced by the production team, the production team could receive 8 fen 9 li in profit assigned to it by the commune. For every 100 jin of food grains over the goals of the responsibility system, the production team could receive a profit of 2 yuan 5 jiao assigned to it by the commune. In connection with increasing the accumulation of indigenous fertilizers, an award of 10,950 yuan was given according to the actual number of square meters of indigenous fertilizers accumulated per season. In connection with the overturning and tilling of grass fields, the quality of summer harvest, summer planting and progress, 4,760 yuan were awarded. In connection with the monetary amount of live hogs sold to the state, 4,900 yuan were awarded. In connection with the number of sows raised, 2,100 yuan were awarded. In connection with the goals of planned parenthood, 7,000 yuan were appropriated. The remaining 7,000 yuan were used as awards for cadres of the brigades and production teams of the whole commune and the heads of contract work groups who have completed the goals of the responsibility system of their post. Commune members engaged in agriculture received a profit of nearly 6 yuan per mu from commune enterprises. The assignment of profits by the brigades was similar to that provided by the communes. This forcefully mobilized the enthusiasm of the commune members engaged in agriculture. Last year, 102 of the 114 production teams of 25 brigades of this commune produced increased output. The total output increased by more than 1.257 million jin, an increase of 7.2 percent. The number of live hogs sold also surpassed the goals of the responsibility system established at the beginning of the year by 33.2 percent.

The number of laborers was determined by the area of the fields. The number of farm workers as a percentage of the total labor force was established by regulation. When the number of people engaged in industrial and sideline production in a commune member family surpasses a certain proportion, the family must pay a fee to supplement agriculture. Commune members who return to farm work are given a salary based on the actual number of work points earned. The Wuyun Brigade of Chengdong Commune has a silk weaving plant, a glass fiber plant, a gauze mask factory and a shipping team totaling nine industrial and sideline units. There was a shortage of workers. To guarantee that agriculture has a sufficient labor force, this brigade implemented the method of determining the size of the labor force according to the area of farmland at the beginning of last year. Ten workers were assigned to work on each 3.7 mu of paddy fields, and 60 percent of the number of workers per family had to engage in farming. The remaining 40 percent of workers of each family were allowed to engage in industrial and sideline production. Salaries were calculated for each family according to this ratio. Families with more than 40 percent of its members engaged in industrial work had to pay an equivalent annual fee of 48 yuan for every 10 workers to supplement agriculture. Families with more than 40 percent of its workers engaged in outside sideline production had to pay an equivalent annual fee of 120 yuan for every 10 workers to supplement agriculture. After implementing this measure, more than 40 people who had gone away blindly to engage in sideline production immediately returned to participate in agricultural production. The labor force for the frontline in agriculture was guaranteed. Cadres and commune members generally said: "Implementing the method of subsidizing agriculture has made people willing to engage in agriculture and industrial work. Agriculture is guaranteed and food grains can increase."

Management of the labor force was strengthened, and the policy of having people engaged in sideline production elsewhere to hand over their economic profits to the brigade was appropriately handled. The personal income of people of some commune brigades who are engaged in sideline production elsewhere is mostly much higher than that of commune members engaged in agriculture at the brigade. In the past, the methods of allowing the workers to hand over only a small portion of the wages to the brigade, of distributing total income according to a scale for equivalent labor within the brigade, and allowing the workers to hand over only a small portion of savings without sharing the social burden were implemented. The methods easily drove some commune members away from participating in farm work. Since the beginning of last year, each commune brigade implemented a method of appropriately increasing the portion of wages earned by people who were engaged in sideline production elsewhere to be handed over to the brigade, and ordering them to submit a part of their wages to offset social costs. The brigades also established regulations allowing people engaged in sideline production elsewhere to receive cash and material rations within the goals of contract production. Those who went elsewhere on their own were also subjected to economic sanctions. Brigades with more people who had gone elsewhere also improved their method of rationing food grains to increase the labor enthusiasm of the commune members engaged in agriculture.

A work post responsibility and awards system for cadres of brigades and production teams and heads of contract work teams was established. Cadres of brigades and production teams and heads of contract work teams generally remain at their work post and cannot go elsewhere to earn extra money. To encourage them to remain and do farm work well, and especially to do the work of food grains production well, the whole city's commune brigades began to establish a work post responsibility and awards system for basic level cadres in farm villages beginning in 1979. Cadres of brigades and production team leaders who have completed the work post responsibility requirements well can receive an award of 20 to 50 yuan per year from the commune and the brigade. Last year, to stimulate cadres of brigades and the production teams to pay further attention to doing food grains production well, rules were established so that those who did not complete the task of the responsibility system in food grains production and those who did not lead in implementing and encouraging the policy of increasing the output of food grains were not awarded. This year, the work post responsibility system for cadres was again enlarged in scope to include heads of contract work teams. Now, most of the localities have implemented this measure.

In rationing materials, more benefits were given to commune members engaged in farming. To encourage the enthusiasm of increasing the output of food grains, more benefits in economic rations were given to commune members engaged in agriculture, and the spirit of emphasizing agriculture was also manifested in rationing food grains, edible oil and sideline products. Most commune brigades did the following: Industrial and sideline workers enjoyed only rations of food grains for contracted work. The rations received for that part of the work over the contract were given to the commune members engaged in farm work to enjoy. Industrial and sideline workers of some of the brigades receiving less food grain rations for contract work were allowed to enjoy a part of the rations for surplus output, but they had to purchase the rations at negotiated prices (the difference in price was generally paid for by the brigades or enterprises). The second was that at some commune enterprises, workers were allowed to enjoy food grain rations within the guideline for contract work. A part of what they received was provided according to food grain rations based on the amount of labor. The commune subsidized the difference in markup submitted by the enterprises to the commune and paid the production teams or subsidized the production teams according to a certain percentage of the basic wages of commune members engaged in industrial work. The third was that some brigades had more food grain rations according to the amount of labor performed within the guidelines of contract work, so they first withdrew a part of the rations according to the number of work points for engaging in farm work. The rest was shared by all agricultural and industrial sideline professions. The fourth was that some commune brigades had less land, and their tasks of food grains procurement were heavy.

Therefore, the basic rations of food grains were appropriately lowered (but not less than a per capita average of 450 jin) and the rations based on labor performed by commune members engaged in farming were increased.

Measures to increase agricultural output which have a higher cost but which have produced visible results are subsidized by the commune brigades. In recent years, many commune brigades of this city implemented appropriate methods of subsidies by communes and brigades according to the needs to expand nylon cultivation of seedlings and to increase the application of phosphorous and potassium fertilizers to reduce the burden of the production teams and to stimulate the development of food grains production. The Guanshi Commune subsidized half of the expenses of the agricultural teams for 80 jin of phosphorous fertilizers and 10 jin of potassium fertilizers per mu. The Zhoujiawan Brigade of Taoan Commune subsidized half of the expenses of the agricultural team to purchase thin nylon sheets to expand nylon cultivation of seedlings.

BRIEFS

DIVERSIFIED ECONOMY--Jiaxing Prefecture, Zhejiang, actively develops diversified economy. During the first 4 months this year, the prefecture had procured 67 million yuan of farm and sideline products for the state, marking an increase of 16 percent as compared with that in the same period last year. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 24 Jun 82 OW]

PRODUCE TARGETS--As of the end of May, 182 million jin of barley, wheat, broad beans and peas had been purchased from Zhejiang Province meeting 36 percent of the total purchase target. At the same time, 80.05 million jin of rapeseeds had been purchased from the province; this was 3.5 million jin more than the purchase made by 31 May 1981. TITLE: "The Soil Regions of China"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 2, 1982 pp 97-109

TEXT OF ENGLISH ABSTRACT: The present paper deals with the principles and methods of regionalization of soils in China. The soil resources of the whole country may be delimitated into three high level categories, i.e., I. Great soil zone; 2. Soil zone; 3. Soil region.

First, the whole territory of China is divided into four great soil regions based on the main variation of soil features and natural environments, namely, I. Allitic great soil region (or ferrallitic great soil region); II. Siallitic great soil region; III. Arid great soil region; IV. Alpine great soil region.

Under these four great soil regions, different soil zones (or soil belts) are divided mainly according to the zonal soil types and their related bioclimatic conditions. The soil zone is further subdivided into soil regions. Each region

[Continuation of TURANG XUEBAO No 2, 1982 pp 97-109]

represents a different soil sequence and related landscape. The utilization, management and ameliorative measures in a soil region are generally similar. The delimitation of soil regions is as follows:

I Allitic great soil regions
    I_1 Latosol zone
        $I_1(_1)$ Phospho-calcic soil region of South China Sea Islands
        $I_1(_2)$ Latosol and mountain yellow earth region of southern Hainan Island
        $I_1(_3)$ Latosol and paddy soil region of southern Taiwan Island
        $I_1(_4)$ Latosol and paddy soil region of northern Hainan Island and Leizhou Peninsula
        $I_1(_5)$ Latosol and paddy soil region of Hekou and Xishuangbanna
    I_2 Lateritic red earth zone
        $I_2(_1)$ Lateritic red earth and paddy soil region of mountainous and hilly land of northern and mid-Taiwan
        $I_2(_2)$ Lateritic red earth and paddy soil region of mountainous and hilly land of southern China
        $I_2(_3)$ Paddy soil and lateritic red earth region of the Zhujiang Delta
        $I_2(_4)$ Rendzina and lateritic soil region of Wenshan-Debao (eastern Guangxi
        $I_2(_5)$ Lateritic red earth and torrid red soil region of southern Mt Hengduan

ORG: Both of the Institute of Soil Science, Chinese Academy of Sciences, Nanjing

TITLE: "The Agro-ecological Characteristics and Regionalization of the Tai Lake Region"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 2, 1982 pp 110-121

TEXT OF ENGLISH ABSTRACT: The Tai Lake region, lying on the Changjiang and Qiantang delta at the juncture of the north and central subtropics, is an independent agro-ecological region. Through thousands of years of human activities of agricultural practice, this region started from its ecological stage of soil swamping, through the stages of polder farming, cropping of rice and wheat, to a stage of coexisting multiple systems of agriculture, forestry, fisheries and sericulture. An efficient and functional agro-ecological system with stable structure and high resistibility to natural calamities has been formed, which has led to the region's being developed to become one of the most notable integrated agricultural bases in China.

In recent years, a triple cropping system has been adopted extensively regardless of the local conditions, which has resulted in deterioration of soil environment and its

[Continuation of TURANG XUEBAO No 2, 1982 pp 110-121]

fertility. In order to improve this situation, it is necessary to study agro-ecological regionalization of this region. Based on a preliminary investigation in the Tai Lake Basin, four ecological regions are divided as follows:

1. The low mountain and hill region: Topographically, hills and mountains are predominant in the region with diversity of soil types. Side bleached paddy soil is predominant in the region. The fertility level of the soil in the region is closely related to its relief and irrigation conditions. Land utilization should be in accordance with the actual conditions. On the steeper hilly slopes with a thin soil layer, forestation should be the only method of land utilization. On the terraced fields with insufficient irrigation, a cropping system of rice-upland crops should be adopted, while on the paddy fields with good irrigation conditions a cropping system of rice-rice-winter crops may be the best pattern. Only on the fields nearby the villages or in open valleys can double cropping of rice or a triple cropping system of rice-rice winter crops be adopted, however, green manure crops should be arranged in the rotation system so as to maintain the soil fertility.

2. The Tai Lake plain region: This region is mainly located on the plain with a few low mountains and hills. Paddy fields are predominant. With plenty of ponds, lakes, streams and rivers, as well as mulberry groves and orchards, this region is known as a base of rice cultivation, fisheries and sericulture.

[Continuation of TURANG XUEBAO No 2, 1982 pp 110-121]

Although most parts of the region are plains, it is undulating in relief, and the topographical variation together with the difference in water regime, soil type, soil fertility and labor force constitutes the special natural and economic conditions of the region. Stagnating paddy soil is widespread in the region, so the cropping system of rice-wheat should be the main rotation system in combination with a proper proportion of a triple cropping system, while in the area occupied mainly by permeable paddy soil, the proportion of the triple cropping system may be greater.

3. The alluvial plain region: This region includes the alluvial plains along the Changjiang and Qiantang rivers. Percolating paddy soil suitable for the cropping system of rice-wheat-cotton is the major soil.

This ecological region is a production base of cotton, oil crops and cereals. Most of the soils are lower in fertility and sandy in texture. The rotation of rice and upland crops must rationally be arranged in accordance with the local conditions. In order to get high yield of cereal and cotton, it is recommended that green manure crops be grown or interplanted in the rotation system to improve soil fertility, and the triple cropping system should not take up too great a proportion so as to ensure the high production of cotton. At the same time, comprehensive development of forestry, fisheries and sideline productions should also be taken into account.

[Continuation of TURANG XUEBAO No 2, 1982 pp 110-121]

4. Depression and polder land region: Through the long period of human activities, polder fields have been built on the depression area in this region. Crisscrossed by canals and rivers, this region has average elevation less than 4 meters above sea level. Waterlogged paddy soil is the predominant soil, and uplands heaped up by human activities are scattered over the region.

With the difference in microrelief, notable variation in fertility of paddy soils can be found in the region. Due to the development of the drainage system, part of the waterlogged paddy fields with one yield of rice annually has been replaced by the rotation of a double yield of rice and wheat.

However, the surface gleyization of soil is getting stronger because a triple cropping system of rice-rice-wheat is unduly adopted. For this reason, the adoption of a cropping system of double rice of a triple cropping system should be limited to the higher field with good drainage conditions.

The ecological conditions of this region are favorable for integrated development of agriculture and other industries. The mulberry or tangerine groves in combination with fishery pools have been developed in parts of the region, which is a very good system favorable for ecological cycling.

TITLE: "Studies on the Fate of Nitrogen Fertilizer. I. The Fate of Nitrogen Fertilizer in Paddy Soils"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 2, 1982 pp 122-130

TEXT OF ENGLISH ABSTRACT: In both calcareous and noncalcareous paddy soils, the fate of urea, ammonium sulfate and ammonium bicarbonate was investigated in microplot experiments laid out in the rice fields using the ^{15}N tracer technique. The results obtained showed that when the N-fertilizers were surface-broadcasted as basal dressing, the recovery of ammonium bicarbonate was the lowest, while the N-loss was the greatest. The balance sheets of urea-N in the strongly calcareous, slightly acid and strongly acid paddy soils showed that the recoveries in rice plants were 22.3 percent, 27.5 percent and 39.8 percent, the N retained in soils was 30.4 percent, 18.6 percent and 16.4 percent, and the N deficits were 47.3 percent, 53.9 percent and 43.8 percent, respectively. In the two noncalcareous paddy soils, the recovery of ammonium sulfate amounted to 50.1 percent and 58.7 percent, but in a calcareous paddy soil it decreased to 22.5 percent. Obviously, the nitrogen loss through ammonia volatilization in the calcareous paddy soil may play

[Continuation of TURANG XUEBAO No 2, 1982 pp 122-130]

an important role in addition to denitrification. The deep-dressing of granulated urea and ammonium bicarbonate was the most effective method for the application of N-fertilizers. In addition, experiments also revealed that N-fertilizer top-dressed at the middle stage of rice growth gave a high recovery of about 60 percent by the rice plant. Experiments also showed that the loss of fertilizer nitrogen was not significantly affected either by temporary drainage at the vigorous tillering stage or by the application of nitrification inhibitor (CP).

TITLE: "On the Silicon Supplying Capacity of Paddy Soils in South China"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 2, 1982 pp 131-140

TEXT OF ENGLISH ABSTRACT: This article deals with the silicon supplying capacity of paddy soils in south China.

1. The content of SiO_2 in the surface soil extracted by HAc-NaAc (pH 4) for soils with a 5 percent increase of rice yield due to application of Si-fertilizer was generally less than 9.5 mg per 100 g soil. For soils with more than 5 percent increase in rice yield due to application of Si-fertilizer, the critical percentage of SiO_2 in straw was usually less than 10 percent (at the ripe stage).

2. The Si-supplying capacity of paddy soils in south China is divided into three types:

[Continuation of TURANG XUEBAO No 2, 1982 pp 131-140]

The first type is the soil with a low level of Si-supplying capacity. The average available SiO_2 in soil of this type is less than 8 mg, and the SiO_2 in rice straw is about 8.5 percent. Application of Si-fertilizer to rice plants on soils of this type may give more than 5 percent increase in yield. This type includes paddy soils derived from granite, red sandstone and the Quaternary red clay occurring on the second terrace of the rolling hills.

The second type is the soil with a medium level of Si-supplying capacity. The available SiO_2 amounts to 12 mg, while the SiO_2 in plant straw is about 11 percent. The paddy soils derived from the Quaternary red clay occurring on the lower slope and valleys of hilly land belong to this type. When they are heavily dressed with nitrogen fertilizer, Si-fertilizer might give a yield increase.

The third type is the paddy soil with a high level of Si-supplying capacity. This type includes the paddy soils developed on lateritic soils of basalt origin, and those derived from lacustrine deposits and alluvial deposits of the delta regions. Generally the rice plant does not respond in yield to Si-fertilizer on soils of this type.

TITLE: "Status of Potassium Spply of Peaty Soil of Paddies in Jilin Province and the Effect of K-Fertilizer"

SOURCE: Beijing TURAN XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese Vol 19 No 2, May 82 pp 202-208

ABSTRACT: Paddy peaty soil is distributed mainly in the river plains and mountain ravines of the cold Temperate Zone of the Northeast, a low yield soil formed by cultivation of paddy rice in the reclamated ash soil or muck soil. About 2.32 million mu of such paddies are reported in Jilin Province, and 1.06 million mu are in Yanbian Prefecture. Some of these paddies have been used to cultivate rice for 120 years. The yield is generally 300 jin/mu. Problems of stunted seedlings, black withering disease, etc. occur every year. A research project was established in 1976 to study techniques of potassium deficiency diagnosis and potassium fertilizer application for the purpose of resolving the problems of peaty soil all over the province. Analysis reveals that the active potassium content of the topsoil of such

[continuation of TURAN XUEBAO Vol 19 No 2, 1982 pp 202-208]

paddies is only 4.7-8.6, amounting to 1/5 of that of river silt soil. Experimental application of potassium fertilizer (potassium chloride) produces yield increases of 6.7-123 percent. Analysis of the rice plants during various stages of the growth and development period reveals that the low yield condition is not obviously related to the nitrogen and phosphorus nutrition condtion. The physiological disorder of the rice plant induced by ferrous is also mild compared with the disorder induced by potassium deficiency. Application of 14-21 jin/mu of potassium fertilizer, especially during the jointing stage when the rice plant is most sensitive to potassium nutrition is recommended.

TITLE: "Economical Use of Water in the Cities"

SOURCE: Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 2, 1982 pp 4-6

ABSTRACT: Since the liberation, the city water supply in China, including separate water supply systems of industries, mines, and enterprises, has increased 20-fold compared with the supply level of 1949, yet many cities of the country still have a water shortage problem of various degrees. The problem is especially acute in the northern cities, such as Beijing, Tianjin, Dalian, Qingdao, Handan, etc. The continuous drought year after year in Beijing and Tianjin has made the problem extremely intense. The Miyun Reservoir can no longer deliver water to Tianjin and water is now brought in from Huanghe, several hundred km away. This paper explains that the problem of water shortage cannot be resolved by simply finding new source of supply. Industrial use of water amounts to about half of the consumption and a great deal of it is wasted. Ways must be found for industries to use the water repeatedly. At present, only 10 percent of the plants in the country are doing so. Public facilities, such as government offices, schools, etc. must check and repair the plumbing system to stop all leakage. Unified management of a city's water supply and wastewater disposal is also necessary for promoting effective control.

TITLE: "Fully Utilize the Water Resource of Huanghe To Serve the Economic Construction of the North"

SOURCE: Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 2, 1982 pp 8-9

ABSTRACT: The water resource of Huanghe is not very rich but the river is very long. The average annual flow volume at Huayuankou Station is 56,000 million m^3, amounting to 40 percent of the total of the 3 rivers of Huanghe, Huaihe, and Haihe. According to actual measurement data, in a low year the flow volume of that station is at least 27,600 million m^3. Since the liberation, 7 large water conservancy stations have been completed on the main channel of Huanghe, with 138 reservoirs of all sizes. The effective irrigated acreage has been increased from 12 million mu to nearly 70 million mu. In the 10 years since 1972, the flow of Huanghe stopped in the low water stage of 7 years. This is not due to insufficient supply at the source, however. It is mainly due to the imbalance of distribution of rainfall and insufficient regulating capacity of reservoirs. In the near future, the paper suggests that economical use of irrigation water and construction of middle and lower reach control type projects are necessary. In the long run, the problem of transferring water of the south to the north must be seriously studied.

TITLE: "Benefit of Water Conservancy Investments and Ways of Improving the Economic Benefits"

SOURCE: Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 2, 1982 pp 16-20

ABSTRACT: From 1950 to 1979, the total investment in water conservancy, including administrative expenditure, is 78.9 billion yuan. About 60 percent of the capital is used directly to serve agriculture, with 55 percent for irrigation and 5 percent for drainage, and only 3 percent for power generation. The sum is mainly allocated by the state, with a portion of it raised by local jurisdictions. The history of capital investment in water conservancy projects and some problem of waste, about 4-10 percent, are reviewed. The indirect waste must also include the destruction of forest coverage, especially at the sources of streams, unreasonable construction projects of dikes, fields, etc. to block the flow of streams, the random enclosure of lakes to enlarge the cropland, and the increasing severity of water pollution. These problems and the large number of disputes concerning the uses of water are mainly caused by the lack of centralized authority in matters of developing water resources. A series of measures are suggested to resolve these problems so as to improve the economic benefits of water conservancy investments.

TITLE: "General Condition of Flood Prevention in 1981"

SOURCE: Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 2, 1982 pp 38-41

ABSTRACT: The special characteristic of the year 1981 was flooding in the west and drought in the east. In the lower Changjiang Valley, the rainfall in Jun is 30-60 percent less than a normal year. The drought condition is only casually mentioned, however. The bulk of the paper is devoted to descriptinns of the rainstorms, floodwater, and typhoons in the upper reaches of Changjiang, the upper reaches of Hanjiang and Huihe, the southern part of Liaoning, the Sanjiang Plain of Heilongjiang Province, the Zhujiang Valley, and the upper reaches of Huanghe. Damages from floods in various parts of the country are also reported. Finally, the paper summarizes briefly the lessons learned from the experience of fighting the floods of 1981.

TITLE: "The Genesis, Damage, and Control of the July 1981 Flood of Sichuan"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 3-10

ABSTRACT: This issue of the journal is devoted entirely to a collection of papers which summarize scientifically the extraordinarily large flood of 1981 in Sichuan. From late Jun to the middle of Sep, the weather of the province was abnormal. According to the data of hydrological and meteorological departments, the temperature of the basin had been high, the vapor was abundant, the barometric pressure was low, and the atmosphere was in an unstable state just when the circulation above the Eurasian continent began to change to cause the southwestern high altitude vortex to spread into Sichuan and to encounter, later, the cold air invading Sichuan from the northwest. A localized vertical movement was thus created to bring the warm and moist air from near the ground surface upward to come to contact with the high altitude air mass and to condense quickly into torrential rains, more than 100 mm in an area of 1500 km^2 and more than 50 mm in an area of 6000 km^2. The rain of the storm center, Weiyuan County, was 157 mm. In recent years, Sichuan had been suffering from continuous and severe droughts, the areas of distribution of which were very

[continuation of SHUITU BAOCHI TONGBAO No 2, 1982 pp 3-10]

similar to those of the rainstorms of Jul 81. According to statistics of the various affected regions, the total direct loss from the rainstorms amounted to more than 2 billion yuan. The industries, agriculture, transportation, and mining were in serious danger and the entire national economy was threatened. As the aftermath of the rainstorms is being studied, the most serious damage is the washout of the top soil, estimated at 3.5 hundred million m^3. This loss has caused the soil of the slope-land to become very thin, and its fertility and drought-resistance are irrevocably reduced. The paper devotes the second half to discussions of the action and importance of water and soil conservation measures, such as forest protection and afforestation, for the prevention and control of flood damages.

TITLE: "Relationship Between the Sichuan Flood and the Geological Background"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 30-36

ABSTRACT: Information of related departments reveals that in the past 500 years, there have been 132 floods in the valleys of Jialingjiang, Peijiang, and Tuojiang and 17 of these were severe. One of the major reasons for the increasing severity of flood damages is the serious destruction of forest cover to cause grave ecological imbalance. The forest coverage has been reduced from the above 19 percent of the 50's to below 10 percent in Sichuan, and to less than 1 percent in a few counties. Such complex factors as the crust movement, the geotectonic framework, the fold structures, the neotectonic movement, the special action of the lithological characteristic, and the variations of geomorphology are briefly stated . When these geological and geographical conditions are combined with the human activities of logging, farming, and construction and the natural phenomenon of rainstorms, landslides, mud-rock flows, ground fissures, and hillside collapses will occur to destroy engineer structures and to cause giant losses of lives and property. Although the flood calamities have the specially heavy rainstorms as the direct inducement because they raise the water table and increase the movement of subterranean water, the other factors form the background to create the disastrous losses.

ORG: Sichuan Provincial Bureau of Environmental Protection

TITLE: "Protecting Environmental Resources to Develop Local Advantages"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 35-39, 29

ABSTRACT: The flood disaster of 1981 in Sichuan occurred mainly in the 200,000 km^2 of river valleys, where the population is dense, the transportation is convenient, the soils are fertile, and the production is rich. This paper attempts to explain why the flood disaster should be concentrated in this area to cause such severe damages. The answer is mainly that human activities have destroyed the environmental and natural resources to cause an ecological imbalance and to weaken the adversity resistance of the land. The paper urges that this painful experience must be summarized and the lesson learned. There should be an all out effort to afforest to increase the rate of vegetative coverage, to use engineering structures to reduce the force of floodwater, to harness and manage the rivers and streams, and to protect the environmental resources so that this very rich region may be reasonably developed and continuously utilized.

TITLE: "The Genesis, Forecasting, Prevention, and Control of Landslide Caused by the Rainstorms in Sichuan"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 11-17

ABSTRACT: The continous rainstorms of 1981 in Sichuan caused landslides in 60,000 places of 90+ counties all over the province. More than 300 persons were killed, 74,000 rooms of houses collapsed, and 60,000 persons were made homeless. The mountains of Sichuan are lithologically soft and weak and compounded with the human factors of constructing fields on the slopes and of destroying the forest cover, landslides occur very easily during heavy rainstorms such as those of Jul 81. The paper compares landslides with earthquakes and suggests ways of predicting their occurrence. Prevention and control take a long time. Of the 570,000 km^2 of land in Sichuan, 70 percent are mountainous. The basic prevention and control work depends upon the emphasis of scientific education of the local people so that the work of landslide prevention may be carried out persistently and scientifically in order to produce lasting effects.

AUTHOR: XU Junming [1776 0193 0682]

TITLE: "A Preliminary Analysis of the Mud-rock Flow Damage in Sichuan and Its Development Tendency"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 18-25

ABSTRACT: In 1981, mud-rock flows were very active in Sichuan and their damages very severe. The distribution, the general history, the damage, and the principle of occurrence of mud-rock flows in the province are described, with tables and a map to demonstrate the extent of mud-rock flow activities in the various countires. In the 30 years of 1950-79, mud-rock flows caused by human actions, such as logging of forests, quarrying, mining minerals, building power stations, highways, and railways, as well as dikes, reservoirs, etc. have become much more frequent in an extent unseen before the 50's. And, they are becoming even more frequent and more damaging in the 70's. On the average, they now occur in cycles of about every 5 years.

ORG: Pedology Research Office, Chengdu Branch, Chinese Academy of Sciences

TITLE: "Protect Soil Resources so Mankind Can Eat"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 40-45

ABSTRACT: The current conditions of destruction of soil resources in Sichuan are described in terms of soil erosion, soil degeneration, soil pollution, and the diminishing situation of cropland (at a rate of 696.3 thousand mu per year, on the average.) In order that mankind will have food to eat (the sustained cropland reduction in the USA and England is made a part of discussion) the soil resources of Sichuan should be urgently protected. The paper suggests that soil and water conservation, the control of soil degeneration, an increase of application of organic fertilizer to improve soil fertility, and the improved management of the river terraces where the greatest damage occurred in the flood of Jul 81 are matters demanding immediate attention if the rich resources of Sichuan basin are to produce any more food.

AUTHOR: None

ORG: Sichuan Provincial Department of Agriculture

TITLE: "Take Care of Slope Cropland, Control Water and Soil Losses, to Promote Agricultural Production [in Sichuan]"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 2, Apr 82 pp 46-50

ABSTRACT: In the 3 months of Jul-Sep 81, the Sichuan Province suffered several disastrous rainstorms and floods and 12 million mu of cropland had been washed out. Of these 2.2 million mu were destroyed; more than 400,000 mu were turned into piles of rubble, difficult to be used to cultivate anything in the near future. The major reason of this calamity is the changes of atmospheric circulation, but after examination, the authors are profoundly aware that in the province, too little slope cropland was taken care of too slowly by too poor a quality of work. The ability of the region to resist natural calamities was very weak. The fact that the losses from this flood disaster were not successfully cut to a minimum is a bitter lesson. In Sichuan, there has been more than 20 years of experience of constructing and reconstructing the slope land. It is just that the determination was not great enough, there were attempts to do too much too fast, and the quality of the work was not sufficiently high. The paper summarizes the shortcomings of past jobs and suggests new ways of taking care of the cropland on the slopes.

TITLE: "All Out Effort to Restore Vegetation to Safeguard the Ecological Equilibrum"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION]
in Chinese No 2, Apr 82 pp 51-57

ABSTRACT: Judging from the conditions in Sichuan, the increasing frequency of occurrence of such disasters as drought, flood, wind, and pests in such special severity as the summer flood of 81 is inseparable from the serious destruction of the vegetative cover. From the viewpoint of ecological equilibrum, the destruction of vegetation has brought about the following: (1) The lack of forests causes a reduction of mosture and leads to drought· (2) Without trees to slow down the runoff and to store water in the layer of fallen leaves, the ground surface is unprotected against torrential rains to result in serious losses of soil and water. (3) The losses of such forest animal, plant, and pharmaceutical resources are difficult to restore. The paper divides the province into 5 regions: the western highland, the western alpine and ravines, the southwestern river valleys, the marginal basin land, and the interior of the basin. Measures to restore the vegetation in each of these regions are suggested.

ADVICE GIVEN ON IMPROVING FARM MACHINE ECONOMIC RESPONSIBILITY SYSTEM

Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 3, 1982 pp 6-7

[Article by Zhang Caide [1728 2088 1795], Maintenance Department, Ministry of State Farms and Land Reclamation: "Steady Perfection of Farm Machine Economic Responsibility Systems. Ten 'How To's' Once Farms Have Promoted Systems of Responsibility Whereby Responsibility for Farm Machines Is Assigned and Rewards Fixed"]

> [Text] Editors note: Today state farms everywhere have promoted a farm machine economic responsibility system founded on accountings for individual machines in which "contracting, fixeds, and rewards" are the main ingredients for an initial surmounting of tendencies toward egalitarianism in distributions. This has aroused the initiative of farm machines staff and workers, has promoted increased agricultural output and earnings, and has produced rather good economic results. Some new problems have also appeared in the process of implementation while, at the same time, all jurisdictions have also accumulated some new experiences. Diligent study and solution of problems is required. The writer of the present article gathered together and collated "10 how to's," which are provided farms everywhere for reference in perfection of farm machine economic responsibility systems.

1. Once Farms Have Instituted Production Responsibility Systems, How Is The Situation of "Machines Replacing Workers" To Be Handled?

Once farms have instituted production responsibility systems, from cadres to workers efforts are put into saving on expenditures, cutting costs, and giving attention to economic accounting. This is good. But some places onesidedly pit responsibility systems against farm machines, emphasizing great use of labor and requiring "less use of machine cultivation for greater year end distributions." This hurts the bringing into play of the role of farm machines. In order to make fullest use of the role of farm machines, Jiangxinsha Farm in Jiangsu Province did the following: 1) depreciated the fixed assets of individual farm machine farming teams, deducted a percentage for machinery overhauls, and distributed these sums to company size farm teams on the basis of the area farmed; 2) correspondingly lowered machine farming fee rates from the former 1 yuan per mu to 0.65 yuan per mu; 3) linked some of the bonuses of tractor personnel to farm teams, i.e. when farmland work quotas handed down by the farm headquarters have been fulfilled and quality of work meets requirements, 50 percent of the annual average per capita bonus at the local branch farm is withheld and is taken care of by the farm team. When year end amount of work completed and plan norms increase or decrease, bonuses proportionally increase or decrease with them. After deducting 20 percent for payment to higher authority as required when assuming sole responsibility, and after deducting 20 percent as a bonus for farm machine staff and workers, all the remaining farm cultivation team year end profits revert to farm teams on a prorated basis for the area they farmed by machine. Results have been quite good and the amount of machine farming has gone up by more than 20 percent.

2. What Is To Be Done When Small Team Management and Machine Farming Conflict?

In the process of instituting production responsibility system, inasmuch as farm teams use a production responsibility system of sub-group management linking remuneration to output whereby the same plot of land is managed by several small groups, the crops planted vary, planting methods and technical requirements differ, the times of field care are not identical, some use machines while others do not use machines, the machine farming efficiency rate and making the most of economic benefits are impaired. In order to solve such problems, Liangjiazi Farm in Liaoning Province used the "five uniforms" method: 1) Uniform crop varieties. They required all production teams to arrange crop structure on the basis of field plot soil quality and fertility, growing crops of the same variety within a single plot with no wasting of plots on the growing of flowers. 2) Uniform machine farming and technical measures. Machine farmed plots and projects were planned by production brigades. Within the same plot ridges ran in the same direction, rows and plants were the same distance apart; the same amount of sowing and fertilizing was done; and seeds were sown to the same depth. 3) Uniform field care. Thinning of seedlings, weeding, top dressings of fertilizer, plant protection, and such farm work requirements were all completed at the same time on any given plot by the work teams. 4) Uniform arrangements for tractors. Use and allocation of tractors was handled in a centralized manner by the production brigades, and work teams could not tranfer tractors at will. 5) Uniform examination and acceptance. Once work had been completed, each small team conducted a uniform examination and acceptance, and at the end of the year uniform accounting of tractor cultivation expenses was done. Use of the "five uniforms" solved conflicts between those who machine farmed and group management, increasing machine efficiency rates and economic benefits.

3. What Is To Be Done About Conflicts Between the Two Minds and the Two Sets of Account Books of Farm Teams and Farm Machine Teams That Arise Out of Use of Farm Machines For "Cultivating Land for Others" in Agriculture?

In addition to their practice of giving maintenance personnel bonuses for increasing income and economizing on expenses, the Xijiang Farm in Guangxi also practices the giving of bonuses on the basis of output. The proportion of these two kinds of bonuses is as follows: The bonus for increasing income and economizing on expenses is 30 percent, and the bonus linked to output is 70 percent. At year's end, those getting a bonus for increasing income and economizing on expenses withdraw 18 percent as a tractor operator's bonus from expense economizing bonus funds, the remaining 82 percent being proportionately parceled out to each work team on the basis of the amount of work done by tractors in each specialized team for an increase in their incomes. Withdrawal of bonuses linked to output is also done on the basis of the proportional amount of work done by tractors in each specialized unit. For example, if the annual per capita quota for each person in a maintenance squad is set at 2,000 standard mu, and 4,000 mu is done at team A during the year, at the end of the year specialized team A will have overfulfilled production and should be responsible for paying the bonus linked to output of two tractor operators. Since farm machine and agricultural economy benefits are mutually linked, both parties cooperate rather well and are mutually concerned about costs and output, so there is also mutual supervision and mutual assistance in the course of work.

4. What is to be done when identical quota critera are used for tractors, and fixed rewards are instituted for fixed output quotas, but because of differing tractor service lives and technical conditions, inequities result? An example is the inequity resulting when the drain on a caterpillar tractor operator's strength is greater and his work environment more arduous than that of a wheeled tractor driver, yet his bonus is frequently lower.

The 102 Regiment in Xinjiang Province considered tractor service life as most important and set up several categories in light of their technical condition, setting different standards for standard costs per mu. Caterpillar tractors, for instance, were put into three categories in terms of their service life of 1-5 years, 6-12 years, and more than 12 years for which standard costs per mu were set at 0.90 yuan, 1.00 yuan, and 1.05 yuan. For wheeled tractors of from 1 to 8 years of service life, standard profits per tractor per year were set at 1,800 yuan. For wheeled tractors with 9 years or more of service life, annual profits per tractor were set at 1,500 yuan. In addition, the proportional bonus to be given was set at 60 percent of the portion saved in the case of caterpillar tractors and 30 percent in the case of wheeled tractors, with the result that in 1980 average per capita bonus for caterpillar tractor drivers. This made caterpillar tractor personnel content to do strenuous field work, and this year quality of field work and rate of hours work have increased very greatly over last year.

5. Should Bonuses Be Given Individual Tractor Units That Have Overfulfilled Quotas When Tractor Brigades as a Whole Have Not Fulfilled Planned Quotas?

Should individual tractor teams be issued stipulated bonuses for overfulfillment of quotas and tractor teams that have not completed plan be penalized as stipulated when tractor plowing brigades as a whole have not completed plan quotas or have incurred losses, and where will the bonus funds come from? The method used by some farms in Jiangsu Province, including the Huaihai Farm, is as follows: 1) Payment out of previous year surpluses; 2) payment from wages that have been deducted for taking leave for illness or for staying away from work unauthorizedly; 3) payments from penalty payments for failure to fulfill quotas and fines for accidents; 4) payments from juggling of accounts, making withhouldings from the following year's funds to be circulated.

6. What Is To Be Done About Blacksmiths, Fitters, Carpenters, Welders and Such Logistics Personnel Once Tractor Team Personnel Institute Fixed Rewards for Fixed Output?

The 29 Regiment in Xinjiang Province changed the former bad practice for logistics personnel whereby there were no fixed worked quotas, no checks on quality, not accounting for costs, difficulty in judging achievements, and no basis for distribution. They instituted "three fixed and one reward" (fixed personnel, fixed work time, and fixed costs), i.e. considering as gross costs employees' wages, fuel expended, electricity expenses, and depreciation of tools and equipment, planning unit man hour expenses on the basis of stipulated number of days at work and man hours, using this as a standard for per man hour charges. When tractor units requested logistics personnel to do maintenance or repairs, they turned in a "maintenance and repair coupon" in lieu of payment of cash to be carried as income for the maintenance and repair units and as an expenditure for the tractor unit. Both parties verified the number of hours and quality of work, and when quality was below standard, the maintenance and repair team bore responsibility for man hour expenses. When maintenance and repair teams rendered assistance in the fields or in other positions, its earnings were figured on the man hour price rate for rendering assistance. For exceeding man hours or income quotas, or for any portion lacking, proportional points were recorded as a basis for distribution of overfulfillemnt bonuses and other bonuses. Four changes took place after this had been done: Where formerly leaders had to urge workers to do their work, now workers sought out leaders to ask for work. Where formerly workers sat around talking when there was no work to do, now whenever they had free time they went everyplace trying to scare up work. Where formerly there had been little concern about labor efficiency or quality, now every second counted and quality was first. Where formerly leaders had been very busy, now everyone was busy.

7. What Is To Be Done About Management Personnel Following Institution of Responsibility Systems of Fixed Reward for Fixed Output Quotas?

Zhongjie Farm in Hebei Province used a system whereby management personnel practiced a responsibility system linked to various economic criteria and work completion for calculation of bonuses and penalties. In this way all tasks were completed and units incurring losses for maintenance were fewer than the previous year, receiving bonuses at the average level of management personnel at the main farm. After fulfilling all production tasks, all maintenance units without losses received from 10 to 20 percent more bonus. When all tasks were not fulfilled, units with losses and units with units where losses were greater than in the previous year got 5 to 10 percent less bonus.

8. What Is To Be Done About Excess Workforces Following Institution of Farm Machine Economic Responsibility Systems?

Once responsibility systems have been instituted, farm machine staff and employee enthusiasm for care and use of farm machines greatly increases; not only is there a surplus of maintenance personnel following the fixing of the number of personnel and a table of organization, but there is also a great surplus of farm workers as a result of improvement in mechanization levels. At Liangjiazi Farm in Liaoning Province, there was a surplus workforce of more than 1,000 farm machinery related workers and farm workers. They did the following: 1) much agricultural capital construction, investing 270,000 man days, moving 340,000 cubic meters of earth and stone to stop waterlogging on a 22,000 mu area and to sink 35 pump wells; 2) planted trees to afforest 6,600 mu; 3) went in heavily for the livestock industry, expanding teams specializing in the raising of hogs, and building poultry and deer farms; 4) much operation of farm-run industries with an expansion and new construction of repair shops, brick and tile plants, paper plants, and two small collective industries. 5) development of households specializing in the raising of livestock, the number of households specializing in the raising of hogs, chickens, rabbits, sheep and goats now numbering 128. Chabei Livestock Farm in Hebei Province organized its surplus machine maintenance personnel for development of economic diversificiation, and a maintenance brigade from the first branch farm assumed responsibility for the repair of highways. The second branch farm's maintenance brigade undertook responsibility for readying and installing machinery in a powdered milk plant. The third branch farm's maintenance brigade contracted hauling of earth for use in daubing walls. Earnings for the first and second branch teams alone for the first half of the year came to 13,800 yuan, and machine maintenance expenses for the farm as a whole were more than 40,000 less that during the same period last year.

9. How Can Bonuses for Maintenance Personnel Be Equitably Withheld Once Systems of Responsibility Linking Output to Calculation of Bonuses Have Been Institued?

When some farms institute systems of responsibility in which output is linked to calculation of bonuses, they promote agricultural production increases through maintenance personnel fulfilling all work requirements in terms of quantity and quality, and they decide first, second, and third class bonuses for them after excess financial profits have been earned in the same way as for farm workers. But inasmuch as tractor units' work is scattered and the work they do not readily amenable to recognition, the work enthusiasm of tractor personnel is damaged. The 29th Regiment in Xinjiang Province based calculations on the number of days of work attendance, i.e. they used the total number of days of work attendance by maintenance personnel divided by the average number of days of work attendance of the unit to derive the average number of maintenance personnel attending work. Then they multiplied the average number of personnel attending work times the average amount of bonus each person in the unit should receive, i.e. the total amount of bonus each maintenance platoon should receive, after which they distributed bonuses to individuals on the basis of number of days they showed up for work and fulfillment of their tractor quotas. This method of figuring was able to embody in an equitable way both the amount of labor expended by maintenance personnel and the results of their labor.

10. How Can Farm Machine Economic Responsibility Systems Promote Transition Toward Specialization in the Farming Industry?

The 129 Regiment in Xinjiang Province tried out farm machine economic responsibility systems linking bonuses to output that featured machines and specialized contracting. By this is meant farm machine personnel were responsible for the growing of grain crops, accepted output and profit norms handed down by the regimental farm, and were proportionally rewarded or penalized in accordance with regimental regulations. In 1980, the 15 companies of the regiment had 32 farm machine personnel who, in addition to being responsible for the farming of 2,200 mu of cotton, were also directly responsible for 4,152 mu of grain crops from which yields averaged 412.6 jin per mu, 9.2 percent higher than plan norms. Output totaled 1,733,000 jin, an average grain output of 54,156 jin per capita. From a 1,130 yuan loss on grain crops in 1979, the situation changed to a profit of 34,508 yuan, an average per capita profit of 1,078 yuan. In 1981, contracting for 5,195 mu of grain crops was continued, as was the contracting for 220 mu of cotton. Grain output is forecast at 21.8 million jin and ginned cotton at 30,800 jin for a 43,636 yuan profit. When 60,000 yuan in earnings for the use of tractors in helping with work and hauling elsewhere is added to this, total profits come to more than 100,000 yuan, double the 1980 figure. Grain output averaged 62,200 jin per capita and profits set a record 2,565 yuan per capita. Such a responsibility system can foster farm machine personnel able to both operate tractors and to farm the fields, thereby further increasing the potential of existing equipment, increasing the labor productivity rate, and helping the transition to specialization of farming.

NEW TASKS FOR FARM MECHANIZATION OUTLINED

Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 3, 1982 pp 5, 12

[Article by Maintenance Department, Ministry of State FArms and Land Reclamation: "New Tasks for the Agricultural Mechanization of State Farms"]

[Text] National state farm management work forums were held during September and December 1981 at Dongxin Farm in Jiangsu Province (the southern section) and in Beijing (the northern section). Delegates to the forums reported on the new situation of steady development of agricultural mechanization work through reorganization and major equipping while carrying out the program of readjustment. They also reported on new achievements and new experiences gained during the last several years in the strengthening of farm machine management and promotion of farm machine economic responsibility systems. They studied new problems and new tasks under new conditions involving farm machine work. They also conducted discussions of individual topics relating to issues such as systems, regulations and technical policies pertaining to "Regulations on State Farm Maintenance Work," "Agricultural Mechanization Technical and Economic Criteria and Accounting Methods," "Provisional Regulations on Scrapping of Agricultural Machines, Agricultural Machines and Equipment Principles," as well as to depreciation of farm machines and equipment, withholdings of funds for major overhaul and replacement and farm machine economic responsibility systems. The conferees exchanged experiences and studied methods, which strengthened their confidence about further strengthening of leadership and management of farm machine work, about making the most of advantages in mechanized farm production, and about improving economic benefits from farm machine operations. Deputy ministers Zhao Fan [6392 0416] and Meng Xiande [1322 2009 1795] also made reports to the forums on the strengthening of farm mechanization leadership work, which greatly encouraged everybody.

The forum acknowledged that since the Third Plenary Session of the 11th Party Central Committee, as a result of reliance on policies and reliance on science for development of productivity, beginning in 1979 state farms throughout the country began to bring to an end the loss situation that had endured for more than 10 years, agricultural mechanization playing a major role in this. A comparison of 1980 with 1978 in the Heilongjiang Provincial Farm Administration show a more than 5 million mu increase in area sown, and a more than 40 million yuan reduction in total expenditures for machine operations. In 1981 the leading leadership comrades in the Xinjiang State Farm and Land Reclamation Administration placed great stress on carrying out regulations on maintenance work, increasing earnings, and conserving expenses to the tune of more than 17 million yuan in a period of less than 10 months, making a major contribution in turning losses into profits.

Accompanying implementation of the party's various economic policies has been the adaptation of general methods to specific situations by state farms everywhere to build and perfect various forms of farm machine economic responsibility systems, linking the workers' rights and responsibilities closely to economic benefits, thereby arousing the enthusiasm for production of the broad masses of staff and employees for a new situation of increased output, increased earnings, and increased contributions. After 29 regimental farms in Xinjiang Province instituted farm machine economic responsibility systems, four great changes occurred. One was that where formerly leaders urged workers to work, now the workers came looking for leaders to ask for work. Second, formerly when there was no work to do, everybody sat around talking, but now whenever there is a moment's free time, they go all over trying to scare up some work. Third, where formerly people did not take seriously work efficiecy or quality, now they make every second count and quality is first. Fourth, where leaders were up to their ears in work while workers stood at the side and watched, now everybody is busy actively making a contribution.

Growth of farm mechanization has provided the workforce resources needed to promote development of economic diversification. As a result of the steady increase in the level of mechanization at the Liangjiazi Farm in Liaoning Province, a workforce surplus in agriculture and farm machinery of more than 1,000 resulted. The action they took was: 1) large-scale farmland capital construction to which 270,000 work days were devoted for the movement of 340,000 cubic meters of earth to cure waterlogging on a 22,000 mu area and to sink 35 pump wells; 2) planting of trees for the afforestation of 6,600 mu; 3) large-scale raising of livestock, expanding the number of teams specializing in the raising of hogs, and setting up poultry raising and deer raising farms; 4) large-scale farm-operated industries with the expansion and new building of repair shops, brick and tile plants, paper making plants, and two collectively operated small industrial plants; 5) large-scale specialized raising of livestock with 128 households specializing in the raising of hogs, chickens, rabbits, sheep and goats. This promoted development of farming, forestry, livestock raising, and sideline occupations, and for 4 years grain production increased annually, and operations brought profits year after year.

The forum maintained that during the present period of national economic readjustment the program for farm mechanization should be as follows: Effective farming of existing cultivated land, and effective use, management, repair, and improvement of existing farm machinery and equipment to make the most of machine benefits for gradual realization of the "mechanization" of key areas and selective "mechanization." The basic goals are timeliness, superior quality, high efficiency, low cost, and safe production to promote increased output and increased earnings. In order to take further advantage of mechanization, work in the following realms must be taken in hand:

1. Summarization of Experiences to Improve Understanding and To Strengthen Leadership of Maintenance Work and To Build a Farm Machinery Corps

First it is necessary to strengthen political ideology leadership, simultaneously perfecting maintenance and management organizations. All levels of state farm and land reclamation units and farms should have one professionally well versed leader responsible for maintenance work.

Today 250,000 farm machine staff and workers are in the frontlines of state farms and land reclamation. In order to further consolidate and improve the quality of this corps, the following must be done: 1) attention to bringing into play the role of farm machine technicians so that they will have genuine functions, rights, and responsibilities. 2) Maintenance personnel should be maintained relatively stable in their jobs and should not be frequently transferred. In the practice of economic responsibility systems, levels of distribution of rewards to maintenance workers should be higher than that of farm workers. 3) Effective training of all personnel to develop a knowledge reserve. Expenses needed for training should be met in accordance with the stipulations of the 1981 Finance Ministry document, Caiqizi No 212.

2. Full Implementation of Maintenance Work Regulations for Steady Improvement in Management Levels

1) Improvement in quality of field operations with strict implementation of field operation operating rules and regulations, farm machines and farming techniques being closely combined. 2) Farm machine management to be the province of machine crews and maintenance teams with reliance on the masses to exercise care. 3) Setting up of models and commending the advanced, with the launching of a movement for comparison, assessment, and inspection. 4) A combination of spiritual encouragement and material awards, linking the sharing of profits and maintenance personnel income to stimulate and arouse the initiative of the broad masses of staff and workers.

3. Steady Reform and Perfection of Farm Machine Economic Responsibility Systems To Increase Farm Mechanization Economic Effectiveness

State farm machine management and promotion should be based on accounting for individual machines in an economic responsibility system in which "guarantees, fixeds, and rewards" are the main ingredients to play a very great role in giving impetus to improvement of quality of operations and economic benefits from mechanization in a preliminary surmounting of egalitarian tendencies toward "eating out of a large common pot." However, because of a shortage of time, it is necessary to further perfect and give attention to the good handling of the following several points: 1) farm machine organization and form of operations have to be subordinate to the needs of mechanized large-scale production and required concentrations with centralized management, centralized allocation, centralized repair, centralized supply of materials, and centralized accounting making the most of the role of machines. 2) Following institution of production responsibility systems, some farms adopted "contracting of small team operations," and "fixing of output quotas based on groups," each plot of cultivated land divided among several operating teams, the crops varying, production techniques varying, and farming times varying, and conflicts arising in the use of machines.

All levels of leadership should proceed from the overall situation and think about matters in an across-the-board way for satisfactory solution. The Dongxin Farm in Jiangsu and the Liangjiazi Farm in Liaoning adopted uniform crop patterns and unified production techniques, with unified machine operations, and unified allocation of machines and personnel. This was a good experience that can be promoted for use and studied.

4. Improvement of Farm Machine Repair Work To Improve the Good Condition Rate of Equipment

State farm machinery repair expenses annually amount to more than 100 million yuan. An effective job of repairs requires strengthening of the following work: 1) farm machine manufacturing and repair plants should follow a program in which repairs are first, and adhere to service to the grassroots and to agricultural production. While maintaining suitably centralized repairs, they should gradually institute specialized repairing. 2) Revival of the withholding of funds for major overhauls with centralized management by fiscal and maintenance departments, the special funds being used solely for the intended purpose. 3) Adherence to a planned preventive repair system with the formulation of equitable overhaul intervals and technical standards. The intervals for overhauls should be sent according to plans; any advances or delays in the time of overhauls would have to be done on the basis of a technical appraisal and be approved by maintenance departments in charge; otherwise they would bear responsibility for shortening the life of the machines. 4) Comprehensive quality controls in production with work being completed on time, and "three guarantees" instituted. Administratively, fixed quota management and economic accounting should be strengthened.

5. Tapping of Potential, Innovation, and Improvement of Existing Farm Machines and Equipment

1) Replacements should be made according to plan. Economic results derived from replacement should be the subject of all-around study with the formulation of an equitable policy for replacement. 2) The focus should be on technical improvements in existing farm implements to increase equipment performance. 3) Use of new farm machines, promotion of new techniques, and improvement of economic benefits.

Sources of Funds for Farm Machine Replacement and Technical Improvements, and Principles of Use.

1) Funds from basic depreciation should assure replacement of equipment, and they should not be diverted to any other use. 2) Right now the equipment depreciation rate is very low, which does not help technical development. Once the equipment utilization rate has been raised, the depreciation rate should raised and the period over which equipment can be depreciated shortened. 3) Basic depreciation funds should be kept by enterprises for the most part, and all of them used for the replacement or technical improvement of equipment. 4) For equitable use of overhaul funds, technical and economic analysis of overhaul must be done. Should overhaul not make as much economic sense as replacement, the overhaul funds should be used in replacing the equipment.

6. Effective Technical and Economic Analysis and Study of Technical Equipment Policies

Reliable production, advanced technology and economic sense should be part of a piece. Effectiveness of investment in farm machines, effectiveness of the use of farm machines, and ultimate economic effectiveness of farm mechanization are organically linked to form farm mechanization technical and economic evaluation criteria. All jurisdictions should adapt general methods to specific situations to arrive at their own farm machine system and equipment principles, and plans for equipping themselves, hurried at first and slow later on, proceeding in an orderly way step by step, and making economic sense to establish a truly intensive farming base. Leaders at all levels should give attention to original records, quotas of various kinds, measurement statistics, quality inspections, equipment maintenance and repair, and such basic work.

BEIJING

ACADEMY OF AGRICULTURAL SCIENCES INVESTIGATES CORN CROPS

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 1, 17 Jan 82 pp 1-3

[Article by Li Jingxiong [2621 4544 7160] and Pan Caixian [3382 2088 2554] of Chinese Academy of Agricultural Sciences]

[Text] From 25 August to 12 September 1981, the Chinese Academy of Agricultural Sciences organized 25 scientists and educators of the 5 provinces and 2 cities of North China to investigate the summer corn crops in Hebei, Henan, Shaanxi, Shanxi, Shandong, Tianjin, and Beijing for the purpose of understanding the progress gained in recent years in the breeding and cultivation condition of corn and clarifying the existing problems in production so as to develop the yield increase potential still further and to determine the ways and direction of future efforts.

Production and Cultivation

There has been some advancement in corn production. The 7 northern provinces and cities are one of the important corn producing regions of China. In the spring and the summer, 125 million mu of corn are cropped here. Compared with the time of the liberation, the acreage of corn has increased 80 percent. The increase in Shandong and Shanxi is 100 percent while that of Hebei, Henan, and Shaanxi is about 60 percent. With the improved condition of water and fertilizer, the extension of intercropping and crop repeating systems, and the utilization of hybrid seeds, the unit yield of corn in the north has been gradually raised. At present, the average yield per mu of corn in the aforementioned provinces and cities is 429 jin, slightly higher than the national average of 400 jin, and 2.1 times higher than the 136.6 jin national average per mu at the time of the liberation. The increase is also rather obvious when the current yield is compared with the average yield of 307 jin/mu of these provinces and cities a decade ago. Shandong Province now has 32 million mu of corn; the average unit yield is 514 jin, i.e. an increase of 22.6 jin per mu per year in the past 10 years. Hebei Province now has 35 million mu of corn; the unit yield is 376 jin, i.e. an increase of 8.5 jin per mu per year in the past 8 years. Henan now has 25.2 million mu of corn; the average unit yield is 423 jin, i.e. an increase of 14.7 jin per mu per year in the past 10 or 20 years. In Shanxi Province, the average yield of corn per mu has increased from the 170 jin of 1949 to 270 jin of 1959, mainly through some improvement in cultivation management, replacing hard kernel varieties with dent corn, etc. In the 60's, the double-cross varieties were extended to resolve the problem of lodging of such varieties as Jinhuanghou. At the same time, the planting density was increased to raise the yield to 370 jin/mu.

In the late 70's, the unit yield of the 11.46 million mu of corn of the province reached 509 jin. This was mainly the result of increased application of chemical fertilizers. In the past 10 years, the increase has been 14.3 jin per mu per year. Shaanxi Province now has 16 million mu of corn; the unit yield is 370 jin. Compared with the yield of 192 jin/mu 10 years ago, the increase is 17.8 jin per mu per year.

If the Yield of Corn is to be Increased Further, the Medium and Low Yield Areas Must be Taken Care of

According to the observations of the team, the intercropped corn or summer seeded corn generally has a yield of 600-700 jin/mu, with the highest near 1000 jin/mu. In the hilly and mountainous regions of the north where the corn is planted, the land is thin, dry, and sandy and there is a large proportion of low-lying saline and alkaline land. The conditions of temperature, water, and fertilizer of these places are also relatively poorer, the technological and economic capabilites are weaker, and the cultivation management is also very extensive; therefore, there is no way to raise the yield of corn. These are the areas which are dragging an entire province down. In Shaanxi Province, these mountainous corn acreage amounts to nearly 1/3 of total, distributed in Qinling, Bashan, and the North Shaanxi plateau, and the yield is less than 200 jin/mu. In these areas, corn is the major food grain, however. In the eastern Henan, in the region of Yudong, Cangzhou, Dezhou, etc. all the corn fields are sandy, low, saline, and alkaline, and the yield is neither high nor stable. For these reasons, raising the crop yield of the medium and low yield areas should be regarded as a strategic matter. During the entire growth and development stage of corn, the crop is regularly affected by all types of natural calamities. In recent years, the ripening time of wheat has been delayed more than 10 days and because of that soon after the summer corn is seeded, the seedlings are easily damaged by too much moisture. In the middle and late stages, the continuous drizzling weather also easily causes the green crop to be overflowed and wilt. There have been drastic changes in the weather pattern in recent years. The floodwater is frequently early to damage the corn crop of these mountainous areas very severely. These facts should all be included in the contents of breeding and cultivation research on corn.

Changes in Intercropping and Crop Repeating Systems

In areas of the two-crop system with the summer corn as the major crop, the following 2 cultivation systems are generally adopted at present: The first is a system of intercropping corn between mounds of wheat. The acreage of this system amounts to 85 percent in Hebei, 70 percent in Shandong, 62 percent in Henan, and very small percentages in Shanxi and Shaanxi,about one million mu each. Within each of these provinces, the intercropping system gradually decreases in percentage from the north to the south. The interval between the wheat harvest and the corn seeding time is gradually longer toward the north and shorter toward the south. In areas of Tangshan, Beijing, etc. the corn is seeded about 2-3 weeks before the wheat harvest. In the area of Zhengzhou, the corn has to be seeded in the narrow rows of 5-6 cun in width between rows of wheat to cause the schedule to be extremely tight. The second system is to seed corn after the wheat as a repeated crop. This system is adopted in areas where the breeds are properly coordinated and the manpower is adequate. In the western Guanzhong region of Shaanxi, the density of the wheat crop is high and the soils are hard; therefore, the intercropping system cannot be carried out. Hence , after the wheat harvest, the field is not plowed before seeding the corn quickly. Most recently, the trench seeding machine made in Baoji or the row seeding machine made in Wugong have been adopted to seed the corn and apply the fertilizer simultaneously. These machines create a favorable condition for orderly and strong seedlings of corn.

The aforementioned 2 systems of cultivating summer corn have respective advantages and disadvantages; their formation and change are influenced by the factors of the weather, the soil, the previous crop, the breed, the manpower, the tools, and the socioeconomic condition. In central Hebei, corn had been simply planted after the previous crop was harvested. In the 60's, late ripening wheat breeds were adopted to replace previous breeds and the system of intercropping high yield late ripening corn had to be adopted to ease the intense labor demand in the summer, to gain bountiful harvests of two crops a year, and to bring no adverse effects on the wheat seeding time. The yield of the intercropped corn is generally 10-15 percent higher than summer seeded corn. The comparative experiment in Shijiazhuang indicated that the normal seeding time of summer corn is only one week later than the intercropped corn but during the seedling stage, the seedlings of the formerare weak due to too much moisture and in the late stage, due to the extremely hot weather, they are severely damaged by viral diseases and the fruit tassels are smaller. When the corn is intercropped, the mounds of wheat prevent the irrigation water to be evenly distributed, the seeding work is too difficult to be of good quality, etc. Such phenomena as missing seedlings, uneven size of seedlings, etc. easily occur. In case of early seeded corn, the period of symbiotic growth of corn and wheat is relatively long; therefore, the young seedlings of corn are often weakened in the competition and their growth in the later stages is affected. At present cases of reverting from intercropping to repeated corncrops are by no means rare. The key is a proper cocordination of breeds and mechanical equipment. In Shandong, with the extension of the early ripening high yield breed of Luyuandan No 4, in many cases, the intercropped corn system has been quickly changed to the system of seeding corn after the wheat crop. In Beijing, the ratio of intercropped corn is very large. Some communes and brigades experimented with direct seeding of the breed Jingzao No 7 after the wheat harvest. The growth and development period of this corn breed was long and the mechanical capacity was insufficient so that less than 1/3 of the acreage could be thus seeded. The Doudian Brigade of Fangshan acquired all the needed machine tools by cooperating with other units before an experiment of summer seeding of corn in 4,000 mu was carried out in 1980. A great harvest of an average yield of 1,065.5 jin/mu was obtained. This brigade had experimented with Jingzao No 7 3 years previously, the yield of direct seeding was 100-180 jin/mu higher than that of the intercropped crop of the same breed.

A Great Deal Can be Accomplished by the Cultivation Technique

The common problem of areas of the dual system of corn [and another crop] is the decreasing soil fertility, the shortage of fertilizer supply, the deficiency of phosphorus and potassium, and a low plant density. In Guanzhong Prefecture, 60-80 percent of the total cultivated land contains less than 1 percent organic matter. The method of returning the stubble to the land was experimented but it could not be extended due to the fact that the problem of fuel shortage was intensified by this method. The region of Huixian and Boai of Henan also has the problem of decreasing soil organic matter content. Although the chemical fertilizer supplement is plentiful the high plant density remains a competing factor to cause the current yield level of 900 jin/mu difficult to break. The application of chemical fertilizers is traditionally heavy in the summer and light in the autumn. The intercropped corn is applied with very little fertilizer to produce the result of delaying the wheat crop for keeping it green longer, while in the late stage of the corn crop, fertility is seriously deficient. When more phosphorus fertilizer is applied for the corn crop, it can balance the nitrogen fertilizer to promote early ripening and has a great effect on the late ripening corn crop. The soils of Shaanxi have a phosphorus content of 400/1,000,000. During the jointing and heading stages, the soil nitrogen content is set at 600/1,000,000 as the fertility standard and this standard often cannot be reached for the majority of the fields. At present, corn-soybean intercropping system is being experimented in many places. This system may be significant in terms of nurturing the soil and taking care of the needs for grain and beans at the same time. Yield increase is closely related to the technique of coordinating plant density with the quantity of fertilizer application. In Hebei Province, the density was only 2,000 plants/mu in the 50's; in the 60's it was raised to 2,700 plants/mu. It has been raised to above 3,000 plants/mu in recent years, while for early ripening breeds, it has reached above 4,000 plants/mu. In the high yield county of Xinxian of Shanxi, the average density of Zhongdan No 2 is 2,143 plants/mu and the yield is not as high as that of Dunliu, a low yield county, having a density of 2,840 plants/mu. In Shaanxi, the density for corn is generally no higher than 2,000 plants/mu; in Guanzhong, it is less than 2,500 plants/mu for even the high yield areas. The densities are; therefore, considerably less than the optimal density of 4,000 plants/mu determined by the result of experiments. For this reason, a suitable adjustment of density should be one way of raising the yield level of corn in the entire province.

Breeding, Breed Certification, and the Production of Seeds

A batch of superior breeds have been selected and bred out and some new combinations have been produced. After a period of using superior breeds to replace farm breeds, China's corn breeding work has undergone the 3 stages of interbreed hybridization, double cross breeds of inbreed lines, and single cross hybridization. For the purpose of simplifying the breeding process and the seed production procedure, the period beginning in the late 60's was devoted mainly to selecting, breeding, and extending single cross breeds to raise the yield of corn still higher. At present, the proportion of hybrid corn is very large in the northern provinces and cities. It is 96 percent in Henan, 90 percent in Beijing, 88 percent in Shandong, 84 percent in Shanxi, 83 percent in Tianjin, 76 percent in Hebei, 75 percent in Shaanxi. In recent years, a batch of superior single cross breeds have appeared one after another. They really have the superiority of being broadly adaptable and obviously yield increasing. Of these, the ones in excess of or close to 10 million mu in cultivated acreage per year include Zhengdan No 2, Danyu No 6, Zhongdan No 2, and Luyuandan No 4. Those having been extended to several million mu include Yunong No740, Jingcha No 6, Yushuang No 5, Shaandan No 7, Lusan No 9, and Jingzao No 7. Those having been extended to less than 1 million mu include Jidan No 3, etc. Compared with the foreign breeds introduced to the region for experimental cultivation, these hybrid combinations are better regarding adaptability, disease resistance, production potential, and kernel quality etc. The parents of hybrids used in production in China are mostly inbred lines selected and bred out in China.

The Joint Regional Summer Corn Experiment of the North has demonstrated that new combinations having relatively better expressions include Xindan No 14, Guandan No 3, Shaandan No 9, and Yandan No 15. All obviouslyhave a promising future. Those breeds that are being tested in various areas include Hudan No 1 (the same as Yandan No 14,) Jinxia No 1 (the same as Liaoyu No 5,) Lindan No 8, Changdan No 19, and Xinhuangdan No 56. Each of these has its own superiorities and all are being emphasized. Of these, Xinhuangdan No 56 produced extremely large ears of 37 cm in length. Those who saw them exclaimed thatthey had never seen anything like it. Several white kernel breeds, Taidanbai, bred out in Taiyuan also have large ears and are suitable as spring corn. They may be experimented within high fertile fields. Moreover, Yuanwu 02 x Jin 402 hybrid has been bred out in Tianjin and 107 x Huangzaosi in Yi County; both are demonstrating excellent qualities locally. They are worthy of attention.

Carrying out Breeding Work to Reduce the Cost of Production and Improve Purity of Seeds

Before the productivity of the parents of inbred lines can be raised, the cropping of single cross hybrids in production is not a practice in keeping with economical principles. The genetic foundation of a single cross is relatively narrow causing it to be unable to adapt to new diseases and pests or to withstand the attack of natural calamities. For this reason, many breeding units have experimented with many triple crosses and double crosses to supplement or replace single cross hybrids. Some combinations, such as Lusan No 9 and Yushuang No 5 have already been used in production. Others, such as Cangsan No 1 (Luyuandan No 4 x Huangzaosi,) Luyuandan No 4 x Guanhuang, Huangzaosi x Sansui/Guanhuang, 206 x Ba912 x Bai MO 17, MO 17 x 334 - 1/Zong 737 (all of which are combinations yet to be named by the breeder unit) still require further experimentation and certification. The utilization of male sterile corn can save the detasseling labor as well as improve the quality of prepared seeds. After the introduction of new C type cytoplasmic male sterile materials in 1974, the work of conversion was launched in the various areas. To date, it has been successful with regard to Yunong 704, Zhengdan No 2, Zhongdan No 2, and Jinxia No 1 and the results have begun to be extended. The male parent in the breeding line of these combinations, the 525 Huobai, the 330, and the Yuanwu 02, happens to be the natural line restoring the C type.

Determining the Breeding Target

It was in 1966 when the corn crop was attacked by the large spot disease for the first time, the importance of breeding disease resistance became commonly acknowledged, and such disease susceptible breeds as WF 9, W 24, 38-11, etc. began to be eliminated. Those that were selected in China, such as 525, Tangsipingtou, and 330, demonstrated their superiority then. In order to overcome the regular threat of the small spot disease to summer corn, Huobai, Huangzaosi, and Yuanwu 02 were created. They were suitable as early ripening and highly compatible parents. In North China, head smut had traditionally been a severe disease of spring corn and all breeds extended before 1975 were susceptible. After the MO 17 inbreed line was used to form combinations, the hybrids were not only capable of resisting head smut, they were able to resist large and small spot diseases as well. Various types of viral diseases and green wilt extensively occurred, however,to present new and even heavier jobs for the crop breeders. It appears that the target of simultaneous resistance to 4-5 different diseases is difficult to accomplish for the time being. In corn breeding, the target should perhaps be, as much as possible, resolving the problem of 2-3 major local diseases or pests. When white kernel corn is being selected and bred, the goal should be to meet the desire of the farmers of the wheat-producing regions. This is a special characteristic of China. At present, white and yellow corn breeds are being combined in hybridization although the market price of the mixed colored corn makes it unfavorable for [State] purchase and its nutritional value is also inferior to all yellow corn. In the majority of the provinces and cities, the farmers strongly demand early ripening, high yielding white kernel corn. Early ripening, high yielding, stable yielding, adaptability, and adversity resistance remain common and important goals of corn breeding. As it is mentioned in the previous section of the paper, early maturity is the reason for Luyuandan No 4 to be quickly extended and to cause the intercropping system to reverse to the repeat crop system. Under the condition of the intercropping system in Henan, however, there remain 20 to 40 days after the corn harvest before seeding the wheat to allow the corn crop to grow longer; therefore, it is not suitable in Henan to overemphasize early maturity. The way to do it is to coordinate early, medium, and late breeds.

Aside from the common targets of crop breeding discussed above, a few units in the north are also proceeding to breed for quality (emphasizing high lysine content) and stalk shape (including short stalk, straightly standing leaves, ideal appearance, double-tassel, etc.) and some preliminary successes have been obtained. These tasks are still in the research stage, however.

Emphasizing the Sources of Breeding Materials and Opening up New Ways of Crop Breeding

Due to the fact that materials for crop breeding are limited, there are only a few mainstay lines to be selected out and when new combinations are tried, the phenonmenon of repetition seems to be difficult to avoid. As a result, most superior combinations have a common parental inbreed line. Three hybrids formed by three main lines are listed in the following table to explain that there is the danger of a hidden genetic weakness in the current and future corn breeds of the north.

Huobai	Mo 17	Huangzaosi
Tangsipingtou x Huobai (Zhengdan No 2)	Mo 17 x 330 (Zhongdan No 2)	Huangzaosi x Luyi-3 (Jingzao No 7)
2578 x Huobai (Jidan No 3)	Gonghuo 412 x Mo 17 (Xindan No 14)	Huangzaosi x Santuan (Yandan No 15)
Huobai x Bai525 (Bodan No 1)	Mo 17 x Fengke-1 (Yudan No 5)	Yuanwu-02 x Huangzaosi (Jinxia No 1 = Liaoyu No 5)
206 x Huobai (Shaandan No 7)	Huangzaosi x Mo 17 (Hudan No 1 = Yandan No 14)	Huangzaosi x Guanhuang (Guandan-3)

If this condition is to be changed, emphasis must be given to the origin of the breeding materials to create artificially complex breeds to reconstruct the colony before new superior inbred lines can be selected out. From the hundreds and hundreds of farm breeds of Shaanxi, more than 20 head smut resisting materials have been selected out and some of these have a high compatibility. Moreover, a new line of Zong 737 has been selected out of another compound breed and it also has a very high compatibility. In Xinxian of Shanxi, the old lines of Jin-01 through 09 have been used to produce a compound breed and from which an inbred line Xin-305 has been selected out. It has the ability to resist large spot disease and head smut. The breed Santuan selected in Yantai is also a product of mixed pollination of many lines. Since 1978, 10 compound breeds have been produced through cooperation and the work of selection, rotated backcrossing, etc. is being carried out. Judging from the preliminary reconstructed colony, disease resistance is obviously higher and the yield is somewhat higher also. All these provinces have performed a great deal of work in terms of selecting breeding materials and ways of breeding. Some have adopted the method of extracting a second cycle line from hybrid breeds. In Shaanxi, it is believed that the backcrossing method is easier than breeding out a new line for the purpose of such a simple characteristic in Huobai inbred line as large spot disease susceptibility.

The Problems of Regional Experimentation and Seed Quality

In the past 3 years, experiments in the summer corn regions of the north have been uninterrupted. They have proceeded in the 2 groups of early and medium ripening breeds. There have been serious and detailed studies on field management and identification and not a few superior breeds have been selected and judged for extension. The current problem in regional experimentation is the relatively confused leadership organization. There is no clear delineation of job responsibility and the phenomenon of multiple and overlapping authority exists. In some provinces and cities, the scientific research unit cooperates with the seed company with the former taking on some jobs and the latter providing support in matters of distribution points and expenditure. The work of certification and summarization was performed jointly by both parties. In some provinces, there are not only national and provincial regional experiments, but also similar experiments arranged by different systems and different departments. There are even many sets of experiments with similar contents arranged in the same location to bring unfavorable effects on all the work.

Production demonstrations of many hybrids have been carried out in Jinxian, Changan, Wugong, Yixian, and Fangshan. They grew orderly and well to prove that the work of seed preparation has been satisfactorily performed. The Mo 17 seeds produced by the Yangqu Superior Seed Propagation Farm and the seeds of white kernel breeds of Qianan of Tangshan are high in quality and purity. The work of perparing corn seeds in Yantai Prefecture has earned a very good reputation. In recent years, the method of covering with bags to purify and propagating the seeds by steps has been maintained to keep the purity and quality of the inbred lines at a relatively high level. In other individual places, an imbalanced condtion still exists with some breeds. Due to mixing of seeds, the green wilt disease has appeared in some Zhengdan No 2 seeds, in Luoyang the Yunong-704 is infected with head smut, and the small spot disease has been discovered in Bodan No 1. In Xuchang of Henan, there was an experiment with seeds of Zhengdan No 2 of different degrees of purity to reveal a relative difference of 145 jin/mu, amounting to 30 percent. In Changzhi, a comparative test of 6 breeds demonstrated that seeds of inferior degree of purity may result in a yield reduction as much as 21.4 percent. In some places, due to the fact that the work is not up to par, seeds that are offsprings of hybrids are continuously being used for planting. In these cases, there is no heterosis utilization to speak of.

BRIEFS

TREATING WASTEWATER--China has extensive deposits of ferric sulfate, coal, and multimetal sulfide, and a large number of these are being mined. The ores contain a certain quantity of sulfides, which, after oxidation, often turn into acidic pit water which corrodes pipes and equipment and endangers the health of the workers. When this wastewater is discharged, it pollutes the environment and the source of water supply to produce serious effects on agriculture, fish culture, and industries. The chemical process of the formation of the acidic pit water and its characteristics are described in this article. In most cases, the mines of China discharge this type of wastewater without treatment to which creates serious environmental pollution and great economic losses. In Yuntaishan of Jiangsu Province, for example, the mine discharges 3,000 tons a month to pollute 1,600 mu of cropland. In an average year, the loss compensation amounts to 50,000-60,000 yuan per year, to reach a maximum of 86,000 yuan per year. Some data on the metal contents of contaminated soil are included in the article. Major techniques of treating the wastewater to render it harmless and the practices of some mines, such as Chuanbu Coal Mine of Jiangsu, are also noted. [Article by XIAO Youquan [5135 2589 5425]: "On Pollution and Protection of Acidic Pit Water"] [Beijing SHUIWEN DIZHI GONGCHENG DIZHI [HYDROGEOLOGY AND ENGINEERING GEOLOGY] in Chinese No 3, 15 May 82 pp 7-9] 6168

NEW METHOD OF HYBRID RICE SEED PRODUCTION DETAILED

Guangzhou GUANGDONG NONGMIN BAO in Chinese 20 Jun 82 p 2

[Article by Liu Wenbing [0491 2428 3521]: "A New Hybrid Rice Seed Production Method"]

[Text] There are two current ways of producing hybrid rice seeds. One is the two stage male parent seed production method whereby the male parent is sown at two different times and transplanted at two different times so as to insure that the male and female parents' (i.e. the restorer line and the sterile line) flowering periods coincide. The other way is the male transplanting seed production method whereby the male parent and the female parent are transplanted into different field plots, the male parent being sown at different times and transplanted in different batches, the male parent being transplanted into female parent fields before the female parent flowers so that the flowering periods will coincide for pollination and hybridizing. The two stage male parent seed production method is handier and requires less work than the male parent transplant method of seed production. However, as a result of the influence of climatic, soil, and man-made factors, frequently the two flowering periods do not coincide, with the result that outputs from seed production cannot be assured. By using the male transplant seed production method, coincidence of flowering seasons can be assured; however, it is necessary to set up an additional "field to provide male parents," and a great amount of work is entailed in transplanting the male parents. Furthermore, if one is not careful, roots may frequently be damaged or buds and panicles killed, the amount of pollen thereby being diminished. Consequently, as a practical matter is is difficult to promote this method for large area use.

In order to assure coincidence of the flowering seasons to win consistently high yields from seed production, the Guanqian Commune Hybrid Rice Seed Production Team in Longqi County, Fujian Province designed a three stage male parent seed production method in 1979, resulting in average yields of 196 jin per mu of intermediate hybrid rice production from the commune's more than 240 mu of fields. From the commune's more than 200 mu of continuous tract seed production fields, yields averaged more than 200 jin per mu.

The specific method they used was as follows: The male parent was sown at three different times and transplanted in two batches. In the first batch, plants from the first sowing and the second sowing were transplanted. Male plants from the second sowing were transplanted into a single row, and male parents from the first sowing were transplanted in a row alongside the male parents from the second sowing. Furthermore, for every three plant spaces, one plant was transplanted and two spaces were left blank. In the second batch, male parents from the third sowing were trnasplanted in the two blank spaces left in the row in which male parents from the first sowing had been transplanted. The ratio of male parent transplants from the three sowings was 1:3:2. The second sowing of male parents was done 5 days after the first sowing, i.e. male parents from the first sowing had a seedling age of 30 days; male parents from the second sowing had a seedling age of 26 days; and male parents from the third sowing had a seedling age of 25 days. Six days following the second sowing of male parents, the third sowing of male parents began. The time of sowing of the female parent was decided largely on the basis of leaf blade differences in the second sowing of the male parent.

The three stage male parent seed production method holds the following several advantages:

1. Assures coincidence of flowering seasons. In the three stage male parent seed production method, the first sowing of the male parent is 4 to 5 days earlier than in the two stage male parent seed production method (as determined by visual inspection of combinations). Moreover, in the three stage sowing of male parent, the second sowing of the male parent is 2 days later than in the two stage male parent seed production method. This attenuates the flowering time of the male parent and assures a coincidence of flowering.

2. Attenuation of the male parent full flowering period. Many years observation shows the female parent to have a 12-14 day flowering period, while in the two stage male parent seed production method, the flowering period is only about 10 days. Because the second transplanting of male parent seedlings comes 8 days after the first one in the two stage male parent seed production method, the period of full flowering during each period is only 5-6 days, causing a period of 1-2 days of no full flowering between the first and second period with adverse consequences for pollinization. In the three stage male parent seed production method, the third transplanting is done 6 days after the second transplanting providing for an overlap in full flowering between the first male parent transplant and beginning of flowering of the second male parent transplant, and an overlap between the time of no flowering as yet for the second transplants and the beginning of flowering of the third transplants to assure no interruption in the period of full flowering of the male parent in a 13-14 day period of full flowering. This is virtually the same as the period of full flowering for the female parent for a general pollination rate of 45-48 percent, and as high as 58 percent.

This method has overcome the expenditure of manpower required by the male parent transplant seed production method and the need to set up "field to provide male parents." It has also overcome the shortcoming of an insufficient supply of pollen.

Therefore, the three stage seed production system is in some ways superior to both the two stage seed production method and the male transplant seed production method.

As schematic diagram of a three stage male parent seed production field is as follows:

(2) (1) x x x x x x x (2) (1)

(2) (3) x x x x x x x (2) (3)

(2) (3) x x x x x x x (2) (3)

(2) (1) x x x x x x x (2) (1)

(2) (3) x x x x x x x (2) (3)

(2) (3) x x x x x x x (2) (3)

(1) is the first male parent sowing; (2) is the second male parent sowing; (3) is the third male parent sowing; and x is the female parent.

INCREASES IN MARKETING AQUATIC PRODUCTS NOTED

Shijiazhuang HEBEI RIBAO in Chinese 26 May 82 p 1

[Article: "Tremendous Increases in Output, Procurement, and Marketing of Cangzhou Prefecture Fishing Industry. State Purchase Quotas Policy Instituted; Satisfaction of Quotas Linked to Supply of Goods"]

[Text] Cangzhou Prefecture aquatic products units have assiduously carried out a program of taking the planned economy as the key and market regulation as supplementary, have instituted state procurement quota and award sales policies for aquatic productions, and have strengthened market management to win excellent economic benefits. Satistics as of the end of April show increases of 27.6, 71.3, and 60.5 percent respectively over the same period last year in output, procurement, and marketing of aquatic products.

During the past several years, development of Cangzhou Prefecture's fishing industry has lagged. Quantities procured by the state have been small and quality poor, and market supplies short, largely as a result of failure to carry out assigned procurement quota policies, failure to honor award sale policies, and lack of improvements in the management system. This year all levels of aquatic product units and production units in Cangzhou Prefecture have proceeded from desire to improve economic benefits to implementation of fishing village economic policies, taking four actions as follows. First was assignment of assigned procurement quotas and the signing of purchase and marketing agreements. Except for prawns, all of which are to be procured by the state, for all other catches proportional assigned procurement quotas were set. Normally verification was done on proportions of sales for each tide. In the fishing season and for the year as a whole, verification was done on the basis of assigned procurement quota base figures, with amounts in excess of quotas being settled for at a negotiated price. Second was institution of award sales policies linking fishing and materials. For lumber, diesel fuel and such materials required by the fishing industry, a system whereby the greater the quantity of aquatic products surrendered the greater the supply of such materials was instituted, the less the quantity surrendered the less supplied, and nothing surrendered nothing supplied. Third was strengthening of market management for the opening of marketing channels. Both assigned procurement and negotiated procurement were handled by aquatic products supply companies, no other unit having any right to intervene, or being allowed to go directly to fishing communes to do private pre-emptive buying. Production units practicing assigned procurement quotas could not sell in markets, nor could collective products be divided among commune members and sold. Control over small pedlars was strengthened in determined curtailment of unauthorized dealings, and profiteers and speculators were resolutely attacked. All levels of aquatic product supply and marketing units were required to determinedly carry out state delivery plans, with no shipments of inferior products while retaining the good ones or selling the good ones while delivering the poor ones being permitted. Fourth was an intensification of ideological indoctrination of fishermen in the "three concurrent concerns" to overcome and prevent a mentality of selfish departmentalism and individualism for active fulfillment of assigned procurement quotas.

Implementation of policies promoted output, procurement, and marketing. As of end April, prefecture production of aquatic products of all kinds totaled more than 17.95 million jin, a 27.6 percent increase over the same period last year. Procurement totaled more than 6.45 million jin, a 71.3 percent increase over the same period last year. Marketing within the province and in the two cities of Beijing and Tianjin amounted to more than 6.05 million jin, a 60.5 percent increase over the same period last year for a fine showing for the spring fishing season as a whole.

MEASURES TO CONTROL SERIOUS COTTON APHID OUTBREAKS OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 28 May 82 p 2

[Article: "Tremendous Outbreaks of Cotton Aphids; Need For Strenuous Efforts in Elimination and Control. Provincial Agriculture Bureau Comrades In Charge Issue Statement to Newspaper Reporters on Current Elimination and Control of Cotton Aphids"]

[Text] On 26 May, Provincial Agriculture Bureau comrades in charge pointed out the following in a statement issued on the problem of elimination and control of cotton aphids [Aphis gossypii]

By now most cotton seedlings in the province have emerged from the ground and a general outbreak of cotton aphids has occurred. Monitoring reports for the period 10 to 19 May from plant protection stations everywhere report a general 20 to 30 percent and a maximum 100 percent plant aphid infection rate. One hundred plants showed aphids numbering more than 100, and many had between 4,000 and 5,000. Curling of leaves has begin to appear on large numbers of plants. A survey done on 19 May at the Zhengding Stock Variety Farm showed a 50 percent rate of leaf curling. Generally speaking, when the plant aphid rate reaches 30 to 40 percent, when aphids number 1,000 per 100 plants, when the number of plants having curled leaves stands at 20 to 30 percent, and when the proportion of ladybugs is less than 1:150, prevention and control should be done at once, otherwise a loss in yields may result.

Aphid pest growth and development in cotton seedlings extremely damages cotton output. Studies show that when aphid pests occur in cotton seedlings during the period between the seed leaf and the first true leaf stage, the squaring stage will be delayed by from 5 to 10 days. When aphids strike cotton seedlings between the seed leaf and third true leaf stage, squaring will be delayed for 11 to 15 days. Surveys done at Shijiazhuang, Handan, Jingtai, and Baoding prefectures show that unless cotton seedling aphids and hot weather aphids are controlled, cotton output will drop by 60 percent or no crop at all will be harvested. If not properly controlled, a 10 to 30 percent drop in output will result.

Control of cotton aphids during the seedling stage requires comprehensive control measures. From the time that thinning of seedlings begins in cotton fields, control of aphids should be done at the same time. When thinning seedlings, attention should go to thinning of cotton seedlings bearing aphids, and uprooted aphid-infested cotton seedlings should be taken out of the fields and buried or composted.

Chemical control should emphasize stem applications of omethoate and methamidophos. Use of this method is highly effective, economical, convenient, and is not limited by lack of pesticide equipment. Peasant households can use it. Chemical control must be done in the control period, neither too early nor too late. In places where the proportion of ladybugs is greater than 1:150, attention should go to protecting and using natural enemies to effect control.

Control of aphids requires use of the plant protection organization. Particularly necessary is bringing into play the superiority of production brigades and production teams in providing centralized control. No matter the forms of production responsibility systems practiced, elimination of insects requires centralized survey of the insect situation, centralized purchases of pesticides, centralized management of pesticides, centralized preparation of insecticides, and centralized organization of control in order to reduce the incidence of accidental poisoning, improve control results, and solve problems of myriad households not having sufficient pest control equipment and inability to control the insects. Leaders at all levels and plant protection units must organize their mainstay cadre forces to go into communes and brigades to provide technical guidance and technical education. They must do a really good job of publicizing safe use of pesticides to prevent accidental poisonings.

GUIDELINES PROVIDED FOR DISTRIBUTION OF SUMMER EARNINGS

Shijiazhuang HEBEI RIBAO in Chinese 22 May 82 p 1

[Article by Commentator: "Concurrent Concern For the Interests of the Three In Doing an Effective Job of Summer Earnings Distributions"]

[Text] Soon the work of distributing summer earnings will begin. In line with the principle of concurrent concern for the interests of the state, the collective, and individual commune members, effective distribution of summer earnings possesses major significance for implementation of party policies, consolidation and perfection of production responsibility systems, for arousal of enthusiasm for labor of commune members, and for further winning of a bumper harvest in agriculture for the year as a whole. All jurisdictions should promptly prepare to do a good job of distributing summer earnings.

This year distribution of summer earnings is being done in a situation in which universally instituted rural systems of responsibility linking output to calculation of remuneration have entered a stage of consolidation and perfection. As compared with previous years, there are numerous new problems requiring study and solution. All levels of leadership should promptly set about investigating and studying to understand base figures. Specialized rural work teams in each county should also make distribution of summer earnings the focus of their activities, focusing on helping grassroots level cadres solve a group of real problems so as to assure smooth progress in summer earnings distribution work.

This year's summer earnings distribution work must be conducted with adherence to the principle of maintaining and consolidating development of the collective economy. In some places grassroots cadres onesidedly suppose that now that responsibilities have been assigned to households there is no longer any need for accumulations. In production teams that practice the contracting of work tasks to individual households, in particular, insufficient withholdings have been made and in some production teams there have been no collective withholdings. It has to be realized that no matter the form of production responsibility system practiced, all economic activities are conducted with adherence to the path of socialism and public ownership of the major means of production such as land. The collective economy can gradually become strong only as responsibility systems are steadily improved and production steadily develops; the collective economy positively cannot be weakened.

The reasons are very clear. Only through steady development and strengthening of the collective economy can commune member contracting activities be securely backed. Therefore, effective collective withholdings and development of a robust collective economy are not only requirements for strengthening the socialist system, but also fit in with expansion of the peasants' long range interests. In the process of this year's distribution of summer earnings, it is necessary first of all, to resolve problems remaining from last year, raising the matter of required withholdings. In cases where individual commune members refuse to hand over withholdings, they should be patiently persuaded and educated. When persuasion and education do not bring them around, the collective should take back the land contracted to them. It is necessary, in addition, to institute withholdings one by one for this year. Generally withholdings will include the following: state purchase quotas, assigned procurement quotas, and agricutlural taxes for grain, oil-bearing crops and other agricultural products sold to the state; public accumulation funds, public welfare funds, and management expenses (including remuneration to cadres); subsidies to various categories of people; depreciation of fixed property; farm implement overhauls; some production expenses advanced by production teams, seeds, livestock feeds, supplemental grain for commune member hog raising, newly sunk production team pump wells, investments in afforestation and a certain amount of obligatory labor and capital construction labor. Today, many places use earnings from sideline occupations to offset withholdings where sole responsibility for work tasks has been assumed. Accounts must be squared and everything about them made public; otherwise, not only will expansion of industrial sideline industry reproduction be at a disadvantage, but it will be difficult to do cost accounting for agriculture. When withholdings are made from production teams, all items for which withholdings have been made, as well as numerical amounts, must be made public to the masses and be subjected to mass scrutiny. Simultaneous with an effective job of collective withholdings, effective arrangements for commune member distributions must also be made, and an effective job done of looking after the dependents of martyrs, servicemen, and hardship households. A portion of commune and brigade industrial sideline occupation earnings should be made a part of commune member distributions. In production teams practicing assignment of full responsibility to households, how these funds will be distributed to commune members must be arrived at through discussion among commune members to find suitable ways. In making distributions, attention must be given to equitable calculation of compensation for personnel in each sector.

Conscientious honoring of contracts is a new feature of this year's summer earnings distributions. Last winter and this spring in a substantial portion of communes and brigades in Hebei Province as a result of the signing of contract agreements between collectives and commune members, state purchase quotas, assigned procurement, collective withholdings, commune member bonuses and penalty payments, and calculation of remuneration became a part of agreements. In making distribution of summer earnings, in all cases in which agreements specify that one thing or another must be honored, it must be conscientiously honored as stipulated. Commune members are to be helped with threshing and with verification of outputs to provide a basis on which agreements may be honored. Should severe natural disasters occur and it becomes difficult to make withholdings in accordance with agreement stipulations, following democratic discussion and agreement among commune members withholdings may be deferred until year's end or reduced. In cases in which commune member distributions cannot be readily honored in accordance with previous agreements, contract norms may be revised through democratic discussions among cadres and commune members before distributions are made. Conscientious honoring of agreements is important in maintenance of the solemnity of agreements and in winning the confidence of the peasants, and no one may scrap agreements on any pretext whatsoever.

Finance and accounting personnel capabilities bear directly on summer earnings distribution work. Therefore, all jurisdications should take the opportunity that the time remaining before the wheat harvest affords to qualify finance and accounting personnel and to set up statistical accounting forms. They should also effectively train finance and accounting personnel. In the course of training, they should be guided to the study and analysis of local realities so they will know what to do about problems that may come up in future. Professionally, they should be helped to understand difficulties so they will be able to meet new circumstances and smoothly carry out summer earnings distribution work. Finance and accounting personnel should also be helped to combine summer earnings distributions with the straightening out of fiscal matters. During the past 2 years, a considerable number of the province's communes and brigades have carried out fiscal reorganization, winning definite results. However, this has not been done evenly. Some communes and brigades did not do this, so their fiscal affairs are still in a chaotic state and losses are severe. This year these places should begin with summer earnings distributions to put their financial houses in order for the first half of the year, and following the wheat harvest, they should straighten out the earlier period. As a result of straightening out finances, the collective economy will be able to proceed along a healthy course.

LAMB BREEDING SURVIVAL RATE BREAKS RECORD

Shijiazhuang HEBEI RIBAO in Chinese 28 May 82 p 2

[Article: State-owned Yudaokou Livestock Farm's Lamb Breeding Survival Rate Again Creates New Records This Year. This Year's Inventory Increase Reaches 123.74 Percent, 3.74 Percent Higher Than Last Year"]

[Text] Several days ago a comrade in charge at the Provincial State Farm and Land Reclamation Bureau told the reporter that the Province's Yudaokou Livestock Farm, which last year had the highest lamb breeding survival rate in the country, this year rose another notch again being the highest achiever in the country. Last year the farm mated 15,000 sheep, which produced 19,151 lambs this year with a survival rate of 18,562 lambs, an inventory increase of 123.74 percent or 3.74 percent more than last year. A look at the lamb production situation shows that adult sheep have fattened well and have sufficient milk, so lambs are healthy. This year the farm also had a new breakthrough in its lamb breeding survival rate. At the No 18 Production Team all of the 163 ewes tended by old livestock man Wang Yuchen [3076 3768 5256] were successfully mated, and the survival rate for lambs that were born was 255, the inventory increase resulting from the breeding amounting to 156.44 percent, exceeding by 6.44 percent the record national high for the same trade of a 150 percent inventory increase in the breeding of lambs in a single herd formerly held by labor model, Song Guofu [1345 1948 1381] making him the second national recorder holder at the farm. Now the Yudaokou Livestock Farm is bolstering management of feeding of ewes and of lambs following birth. As lambs increase in daily age, they gradually lengthen pasturing time, and increase time alloted to the collection of grass and the quantity hauled in order to increase milk to promote normal development of lambs.

ALL ENCOMPASSING AGRICULTURAL, COMMERCIAL CONTRACT SYSTEM PROMOTED

Shijiazhuang HEBEI RIBAO in Chinese 24 Jun 82 p 1

[Article: "Shijiazhuang Prefecture Gives All Around Promotion to Agricultural and Commercial Contract System. Commune Members' Minds At Ease; Cadre's Confident, and State Plan Guaranteed"]

[Text] The 17 counties of Shijiazhuang Prefecture have universally promoted an agricultural and commercial contract system. The assortment of goods for which agreements have been signed include grain, fats and oils, cotton, tobacco, live hogs, fresh eggs, pears, apples, red dates, walnuts, and vegetables, diesel fuel, chemical fertilizers, and pesticides. Currently more than 89,000 individual contracts having a value totaling 449 million yuan have been signed throughout the prefecture.

Shijiazhuang Prefecture has used the institution of an agricultural and commercial contract system as a major technique in applying economics to management of the economy. All state owned commercial units (including those for business, supply and marketing, grain, and foreign trade) signed agreements with rural production teams, in accordance with state plan, for the purchase of agricultural products and the supply of materials to support agriculture. Production teams then signed, in turn, contract agreements with specialized teams (or units), or with commune member households, providing for a responsibility system linking output to calculation of remuneration. In this way not only were state plans pertaining to agricultural production put in place in the form of agreements, agricultural production thereby being put on the proper path of the state plan, but state procurement and marketing plans were dovetailed with agricultural production plans to achieve level by level control and clearly defined responsibilities, thereby assuring smooth fulfillment of state procurement and marketing plans and agricultural production plans. People said that with the signing of agricultural and commercial agreements, it is as though commune members had taken a tranquillizer, the cadres had gained confidence, and state plan was assured, all three parties being pleased. The grain and edible oil agreements signed by the prefecture this year account 94 percent of the prefecture's state procurement quotas. Those for cotton account for 103.5 percent of procurement plan; those for tobacco account for 119 percent of procurement plan; those for pears amount to 154 percent of procurement plan; and those for red dates account for 109 percent of procurement plan.

By way of strengthening management of economic agreements and assure their implementation, each county in the prefecture has set up small leadership teams for promotion of the contract system at the county and commune levels. The prefecture, counties, and communes, as well as all pertinent vocational units in charge, have designated and placed in charge leadership cadres and management personnel responsible for contracts work. Each unit signing contracts has established personnel solely responsible for signing of contracts and managing them. Throughout the prefecture a preliminary situation has come into being whereby "leaders are directly in charge of the division of labor, units in charge are in control of specifics; grassroots levels provide designated personnel to take charge; and authenticating units are in overall charge." Recently Shijiazhuang Prefecture's government administrative offices have required each jurisdiction to use various means to organize cadres and masses to thoroughly study "economic contract methods," to enhance their conception of the legal system, and to establish a fine style of "attach importance to contracts and safeguard their trustworthiness," and "fairness and honesty with no cheating of anyone." The prefecture also required that all levels of government and vocational units in charge genuinely strengthen leadership, make periodic inspections, give attention to representative examples, summarize experience, promptly discover and solve existing problems, intensify training of contract management cadres, and steadily improve management levels.

HENAN

PAYING ATTENTION TO GRAIN PRODUCTION COMMENTED ON

Beijing RENMIN RIBAO in Chinese 13 Apr 82 p 2

[Article by Xiao Bingjun [5135 4426 6874] and Sun Xitong [1327 1585 0681]: "Emphasize Production of Millet"]

[Text] As early as the 1950's, there had been records of per mu yield of 1,000 jin of millet in Wen County and Tangying County in Henan Province. Some counties in Shandong, Hebei and Shanxi also had millet fields of unit yields of 500 to 800 jin. Thus it can be seen that as long as the conditions of the climate, soil and water and fertilization are appropriate, and as long as there is scientific management, the yield of millet can be increased. We cannot say that millet is a low yielding crop.

The nutritional content of millet is higher than other food grains and the nutrients have special functions in human health. According to analysis by research units in the health sciences, each jin of millet contains 48.5 grams of protein, 8.5 grams of fat, and a higher content of vitamin B, and the content of vitamin A is especially rich. In our nation's northern farm villages, millet is frequently used as a supplement for pregnant women and babies. People plant millet to harvest the seeds and also obtain more straw. The straw of millet is rich in nutrients. According to analysis: The straw contains 0.7 to 1.0 percent of digestable protein and a total of 47 to 51.1 percent of digestable nutrients. The amount of digestable protein in millet straw is higher than both wheat stalks and rice straws. Millet straw can be easily stored and is an indispensable feed for mules in the northern parts of our nation.

Millet husk is a good feed for hogs and chickens. As long as it is fully utilized, it can conserve a lot of fine feed.

Millet is strongly resistant to aridity. Such a situation frequently occurs. Under the same threat of drought, corn often dies from the drought while millet could still grow.

Millet can be easily stored and carried. It is the best food to prepare for war and disasters. Millet grains have a strong outer shell, and it can be called "the food grain that wears a helmet." Ancient books note that "of all the nine grains in storage, millet is the main one." Throughout the dynasties in our nation, most of the granaries (for disaster relief) stored millet. During the War Against Japan and the war of liberation, millet was the main type of food grain for consumption by our armed forces in the northern regions.

Millet is a superior crop. In readjusting the structure of food grains, we should restore the role and the reputation of millet production. We should provide more area, more water and fertilizers and more efforts of scientific research and management to millet production. We should establish rational regulations in procurement, pricing and evaluation and awards. We should promote a relatively quick restoration and development of millet from many aspects.

SUZHOU PADDY RICE HIGH-YIELDING CULTIVATION POPULARIZED

Beijing RENMIN RIBAO in Chinese 14 Apr 82 p 2

[Article: "Suzhou Prefecture Utilizes the Sirgle Season Rice Cultivation Center as the Center for Demonstration To Popularize Again the Experience of Chen Yongkang To Cultivate High-Yielding Paddy Rice"]

[Text] The fervor to relearn and popularize the experience of cultivating high-yielding paddy rice by farmer-paddy rice expert Chen Yongkang [7115 3057 1660] is surging in the Suzhou Prefecture in Jiangsu Province.

During the last 2 years, Suzhou Prefecture implemented the policies of agricultural readjustment. The area of single season rice has been restored to about 50 percent. Because the broad numbers of cadres and commune members have planted very little single season rice since the 1970's, the techniques of cultivating single season rice have generally become unfamiliar. Starting from last year, the administrative office of the Suzhou Prefecture invited Chen Yongkang to establish demonstration points for the single season rice cultivation center in 8 counties of the prefecture. Each county established 16 experimental sites to learn Chen Yongkang's paddy rice cultivation techniques according to the types of zones.

In the 1960's, Suzhou Prefecture launched activities to learn Chen Yongkang's experience in paddy rice cultivation. Today, the prefecture again organized efforts to learn and popularize Chen Yougkang's experience and further pushed forward the efforts of farmers to learn science and use science. Chen Yongkang's every field conference, reporting meeting or demonstration attracted many farmers. Ordinarily, a continuous stream of people visits his demonstration center to visit and learn.

Suzhou Prefecture has realized preliminary results in relearning and popularizing Chen Yongkang's experience in cultivating high-hielding paddy rice. The unit yield of paddy rice at the 9 demonstration points of the center throughout the prefecture has averaged an increase of 21.4 percent in yield over the unit yield of the large fields planted by the local brigade. This year, Suzhou Prefecture has decided to expand the original demonstration fields of the center to become a model production team and brigade. At the same time, it will invite Chen Yongkang to help train a technical backbone force and "technical families."

SOME TRICKY PROBLEMS IN SUMMER DISTRIBUTIONS HIGHLIGHTED

Jinan DAZHONG RIBAO in Chinese 19 May 82 p 1

[Article by Commentator: "Consider the Interests of the Three in Doing an Effective Job of Summer Distributions"]

[Text] This year Shandong Province's summer distribution work poses many new situations and new problems, the major ones of which are the following: 1. An extremely imbalanced situation in bumper and poor wheat harvests resulting from the serious drought. 2. New developments and changes in forms of agricultural production responsibility systems with a change from distributions according to workpoints to a very large increase in units that have engaged in "contracting, delivering, supplying and keeping in stock." An appreciable number of these did not change their form of responsibility system until after fall planting or even until this spring. Inasmuch as time has been short and experiences inadequate, remaining problems are considerable. 3. The grassroots leadership teams in a minority of units are slack, and some are even in a state of semi-paralysis or paralysis. The above situations demonstrate that difficulties will be great and tasks formidable in doing an effective job of summer distribution this year. All jurisdictions should genuinely strengthen leadership and take vigorous action. They should first effectively investigate and study, and devote efforts to understanding matters pertaining to this year's summer distributions such as the state of grassroots leadership teams, forms of responsibility systems, disaster situations, output, earnings, financial accounts, and cadre and mass thinking so that they will be clear about situations and do a good job about some of them straightaway. Second, they should run various kinds of pilot projects on the basis of different forms of responsibility systems to gain effective experience and provide tailored guidance. Third is attention to weak links, providing major help to those units in which leadership teams are paralyzed or semi-paralyzed, the forms of responsibility systems shaky, and financial management chaotic. When an effective job of summer distribution work has been done so that the party's policies will be carried out and honored, agricultural production responsibility systems can be further stabilized and perfected to stimulate cadres and the masses to use greater zeal in winning an all-around bumper harvest from agriculture this year.

Proper handling of the three relationship, concurrently considering the interests of the state, the collective and individuals, is a fundamental principle that must be upheld in distribution work, and it is also a major indicator in judging how well distribution has been done. Overly high state procurement and overly high accumulations in disregard of the welfare of the peasants dampen peasant enthusiasm. Consideration of peasant interests alone without consideration of the interests of the state or the collective can impair development of production, impair national construction, and in the end can also damage the peasants' long range interests. In this year's summer distributions, handling of the relationships of the three will be manifested more conspicuously in grain than in previous years, and will require arduous and meticulous work to achieve consideration of peasant interests, provide for commune members livelihoods, calm their feelings and encourage their efforts and, at the same time, to do an effective job of collective withholdings and fulfillment of state procurement quotas. Last year, despite a provincewide reduction in grain output, 10 counties contributed more than 100 million jin of grain to the state, and in 14 counties the grain contribution per capita averaged more than 130 jin. These included five counties in which per capita grain contributions averaged more than 200 jin. They supported units in which production of economic crops is concentrated where grain does not suffice, and they supported national construction. Such a spirit of love for the country, love for the collective, love for socialism, and "treating the entire country as a chessboard" should be carried forward. This year those units in which assumption of responsibility for grain quotas is small and increased wheat output great should be mobilized to carry forward this spirit. While assuring no reduction in commune member grain rations and in collective withholdings or even slight increases, they should sell some more wheat to the state. Disaster stricken units with declines in output should also give close attention to these three matters. Last year a small number of units pursued only commune member distribution norms, making no or few withholdings for accumulation. Amounts that should have been withheld were not withheld, or excess distributions were made. As a result, the collective had nothing to work with to the impairment of production growth. This lesson must be borne in mind.

Most important in distributions within the collective economy is implementation of the principle of distribution according to work. Most contract agreements signed this year by most units, production teams, and individual contractors provided for production quotas, remuneration of labor, bonuses and penalties, as well as state procurement and collective withholdings. Contracts embody the principle of distributions according to work and the principle of concurrent consideration for the welfare of the three. They should have the force of law and should be abided by and honored in the course of distribution and not scrapped at will. If serious decline in output as a result of natural disasters necessitates contract revisions, this must also be done only through discussion and concurrence on the part of both parties. Preferential treatment and care of the families of martyrs and servicemen, households enjoying the five guarantees [childless and infirm old persons who are guaranteed food, clothing, medical care, housing and burial expenses by the people's commune], and hardship households bears on cementing of relations between the military and civilians, and assuring social tranquility and unity. It is a major matter that demonstrates the superiority of socialism, and this work must be done well in accordance with policy policies. Production brigade and production team cadres carry heavy responsibilities. All work devolves upon them, and they should be given compensation that is slightly higher than that given for the same labor in the brigade or production team. It is also essential that schoolteachers in schools run by the people, barefoot doctors, and other people providing services in collective enterprises be equitably compensated. In short, distributions are a major link in economic activity, and are the collective embodiment of the party's rural economic policies in rural villages. The time for this summer's harvest is fast approaching, and summer distribution work must be done promptly and effectively.

TIGHT MANAGEMENT OF WATER RESOURCES URGED

Jinan DAZHONG RIBAO in Chinese 21 May 82 p 1

[Article: "Increased Centralized Management to Improve Water Conservancy Benefits. Heze Prefecture Solves New Problems in the Fight Against Drought in the Wake of Fixing Output Quotas Based on Households"]

[Text] In view of the new situation following general practice of production responsibility systems fixing outputs on a household basis or large scale assignment of responsibilities, Heze Prefecture has correctly handled the relationship between centralization and contracting in the use of water to fight drought. It has instituted a system of several centralizations and several contractings for water sources, water equipment, and water conservancy facilities to make full use of benefits from water conservation facilities.

In the course of fighting drought to save the winter wheat harvest and to save spring planting, the Heze Prefecture Committee and government administrative offices learned that all units that had done a good job of launching combat against drought had done so as a result of collective strengthening of water conservancy facilities management and their centralized use. On the other hand, because some units had slackened collective management, had divided up machine pumps, did not have open ditches, and had management that was in a state of chaos, their movement to combat drought and protect the wheat harvest and spring planting had been impaired. In light of this situation, both the CCP Committee and government administrative offices emphasized the need to give attention to "centralization" in the use of water to combat drought. Each of the brigades in the prefecture conducted surveys to find the reasons why units had not "centralized" water for irrigation, giving practical help in solving the problem. In thier use of water to fight drought, each county and commune substantially used a "six centralization" method as follows: centralized planning of water conservancy facilities; centralized construction; centralized management and use; centralized allocation of water resources and water equipment, centralized fee collection standards, and centralized solution to remuneration for operators and personnel tending sluice gates and ditches. All communes and brigades adapted general methods to local situations in centralized form. The method adopted by Libentun Commune in Dingtao County was as follows: Major farmland capital construction projects such as main and branch ditches, culverts, and sluice gates were under centralized organization, management and use of communes, fees being apportioned on the basis of the amount of benefit each unit received. Lateral ditches, sublateral ditches, and small feeder ditches under centrally organized and constructed by brigades. Canals, bridges, and culvert gates were looked after by specific people. Water resources were centrally allocated for centralized use. Centralized use arrangements were made by collectives for production team machines. There were specific operators, specific remuneration, and a well defined responsibility for maintenance and use. Machine repair expenses were paid for out of withholdings. From a foundation of centralized management of its water conservancy facilities, the Sunlaojia Commune in Cao County set up a water conservancy and irrigation service team. The service team was composed of more than 10 people, and each two operators constituted a service unit assigned to a pumping machine (including machine, pump, pipes, and associated tools) under direct commune leadership and centralized direction. Emphasis was on helping units lacking irrigation equipment to gradually set up their own irrigation system and management methods.

As a result of its centralized management and use of water to combat drought, virtually all of Heze Prefecture's more than 300 large water pumping stations, its 86 large and medium size streams, and its more than 40,000 pump wells were in use.

INCREASING PURE COTTON FABRICS PRODUCTION URGED

Beijing RENMIN RIBAO in Chinese 12 Apr 82 p 2

[Article by Shang Daijiang [1424 0108 3068] and Hu Taichun [5170 1132 2504]: "Organize Production According to State Plans; Shanxi Textile Industry Actively Increases Production of Pure Cotton Fabric"]

[Text] Workers of the textile industry in Shanxi Province have correctly handled the relationship between local profits and overall profits, appropriately reduced the output of long staple products according to state plans, and actively increased the output of pure cotton fabric. At present, 908 weaving machines that produce long staple products have been converted for weaving pure cotton products.

The textile industry in Shanxi Province has always been involved mainly with the production of cotton cloth. Pure cotton fabric constitutes over 80 percent of total output. Besides supplying its own province, over half of the products is shipped to other provinces according to state plans. Because the production value and the profits from producing cotton textiles were low, this province has gradually converted more than 1,000 weaving machines to produce fabrics with a high production value since 1979. Up to the end of last year, the output of fabrics of a high production value as a percentage of the total output increased from 8 percent in the previous year to 13 percent.

The Shanxi Textile Printing and Dyeing Plant has a total of 936 weaving machines that produce fabrics of a high production value. According to unified arrangement by the Provincial Textile Department, 600 machines had to be converted to produce pure cotton fabrics. The factory therefore lost more than 300,000 yuan in income. The workers discussed the situation and proposed that as long as the state and the people need such products, no matter how difficult, they will bear it. In less than 1 month, they completed the task of conversion. To reduce loss in conversion to the minimum, the workers of the textile industry in Shanxi exerted efforts to increase the economic gain. The three textile mills of Linfen, Xiangfen, Houma in the Linfen Prefecture launched competitive activities to compete against each other in goals, in accounting, in finding differences, and in developing potential. In January and February of this year, the quality of cotton cloth produced by these three mills visibly improved over that of the same period last year, and consumption of such raw materials as cotton yarn was reduced by a large scale.

SHANXI

JINDONGNAN EXPANDS MILLET PRODUCTION

Beijing RENMIN RIBAO in Chinese 13 Apr 82 p 2

[Article: "Suiting Measures to Local Circumstances, Rationally Arranging Planting, Jindongnan Develops Advantages of the Locality To Expand the Planting of Millet"]

[Text] Editor's Note: Under the guidance of state plans, suiting measures to local circumstances in rational planting is an important principle in guiding and arranging agricultural production. Not only must food grain crops and diversification be rationally arranged, the problem of rational arrangement of food grain crops themselves also exists. The needs of the state and the masses must be satisfied. Characteristics of the natural conditions of the localities must be studied. The advantages must be developed and the shortcomings must be avoided. Superiority must be developed. Expanding the planting of millet in Jindongnan is a measure to develop the superiority of the arid mountain areas and to realize better economic gain. The masses will have millet to eat and livestock will have feed grain and grass. This benefits the nation and the people, and why should we not do such a good deed?

For a time, under "leftist" ideological influence, the Jindongnan Prefecture not only singularly emphasized planting food grains, it also allowed only sorghum, corn and such so-called "high yielding" crops to be planted, and millet was completely prohibited. In this way, one cannot talk about starting out from the actual situation. Today, communes and brigades have a definite autonomy, and under the guidance of state plans, as long as we are skilled at summarizing the experience and at suiting measures to local circumstances, agricultural production in Jindongnan Prefecture will surely develop an even greater potential.

Report by correspondents Wang Jinshui [3769 6855 3055] and Chen Maosheng [7115 5399 4141]: The Jindongnan Prefecture has suited measures to local circumstances in arranging planting, developed the superiorities of the locality, expanded the production of millet, and last year, 160,000 mu were sown, and this year, the area expanded further to about 2 million mu.

Millet is a traditional food grain crop in Jindongnan Prefecture. In the past, farmers planted millet actively and provided a large amount of millet to guarantee the needs of the military and food for civilians and to support the revolutionary war. A leading comrade of the Party Central Committee inspected Jindongnan Prefecture not long ago and pointed out: "The millet of Jindongnan is famous...In the whole nation, millet of northern Shaanxi and the millet of this region are good. I agree with you in planting more millet."

For a long time, under "leftist" ideological influence, millet was also criticized. The sowing area of millet throughout the whole region has lessened by more than 1 million mu since the beginning period of liberation. Even though unit yield has increased, because the area has lessened, the total yield has dropped from the highest annual yield of more than 600 million jin to about 500 million jin. The percentage of the supply of millet has also lessened year by year.

The natural conditions in Jindongnan Prefecture are superior for planting millet. The growth season of millet coincides with the rainy season in the southeastern Shanxi region. Therefore, the yield is more stable than that of corn, sorghum and wheat. Millet is tolerant to drought and waterlogging. Its adaptability is strong, its nutritional value is high, and the masses love to eat it. It can be planted at more than 300 communes throughout the region. Every county and commune has the typical experience of producing bumper harvests of millet. Jinqing Brigade in Huguan County is a dry rock mountain region at more than 1,200 meters above sea level, and it is a place where water sources are extremely deficient and where the frostless period is short. Farmers have developed the experience of scientific planting of millet in practices of autumn tilling to strengthen upturning of the soil, preparing the land for three types of moisture, storing water and retaining the soil, and improving soil fertility. At the beginning of the 1960's, the per mu yield of millet reached 500 jin. Since the 1970's, the per mu yield has remained at above 800 jin. There were 4 years in which the per mu yield broke the 1,000 jin mark. In the year of the highest yield, per mu yield reached 1,041 jin, and the ridiculous theory that "millet is low yielding" has been broken.

Huguan County, which is arid and lacks water, popularized the experience of Jinzhuang over large areas and realized outstanding results. Huguan had a major drought in 1980. Most communes, brigades, people and animals had difficulty in obtaining drinking water. The whole county popularized the experience of Jinzhuang on an overall basis. The average per mu yield of millet still reached 413 jin, and total yield increased by 8.7 million mu. Of the food grains submitted and sold to the state, millet constituted 53 percent. Of the rationed food grains of commune members, millet constituted 35 percent. Everyone responded by saying this is a good thing, which benefits the state and the people.

The committee and the administrative office of the Jindongnan Prefecture was inspired by the large area popularization of the Jinzhuang experience in Huguan County. They calculated that if the area of millet throughout the whole prefecture reaches 2 million mu, the yield would reach the level of output of the 1970's in Huguan County. The total yield of millet throughout the prefecture would reach more than 700 million jin, and 1.5 billion jin of straw could be produced. In this way, the masses would have millet to eat, large livestock would have straw as feed, the husk of millet could be provided as raw material for the wineries, and it could also be used to raise hogs and chickens. The production cost of millet is low, equivalent to only half that of wheat. In the overall balance, planting millet has more benefits than planting other food grain crops.

To expand the planting of millet, the committee and the administrative office of the prefecture held a field meeting on millet production for the whole prefecture at the Jinzhuang Brigade in Huguan County as early as September of last year. Delegates from all localities conscientiously learned the Jinzhuang experience. Before sowing wheat in autumn of last year, arrangements were made to expand the planting of millet. Autumn tilling and upturning of the soil were grasped in a big way, and fertility was accumulated and the land was prepared. At present, each locality throughout the prefecture is actively shipping fertilizers and preparing superior seeds to develop local superiority and seize a bumper harvest in millet, and each locality is carrying out intensive activities to prepare for planting.

FIGHT AGAINST DEEPENING DROUGHT CONTINUES

Tianjin TIANJIN RIBAO in Chinese 17 May 82 p 1

[Article: "Four Thousand Rural Cadres Go Into Frontlines of Fight Against Drought. Cutbacks in Conferences and Temperary Halt to Vacations As Drought Dramatically Deepens"]

[Text] During this serious time of dramatic deepening of the drought, leaders at all levels in the municipality's rural villages have organized 859 suburban and county cadres and 3,677 commune cadres to hurry to the 97 key communes where tasks in fighting drought are heavy, hardships numerous, and potential for increases in yields great to struggle alongside the broad masses of the people against drought.

After these cadres had arrived in the communes and brigades, they first guided the broad masses of people in shoring up their confidence, in overcoming fear of hardships and a psychology of waiting for the heavens to rain, and worked together with the masses to study specific measures to be taken to fight drought, and solve genuine hardships in the work of fighting drought. In order to make the most of benefits from existing pump wells, principal leaders in Wuqing County diligently increased pump installations, changed pump diamters, tightly sealed pipes going into the well at the wellheads, and refitted center line wells. They led the masses in self-reliantly changing existing pumps, giving new life to 497 dead wells from which no water flowed as a result of a drop in the water table for an 18,000 mu expansing of the irrigated area. Ji County CCP Committee Secretary Wang Shuliang [3769 2885 5328] went to seriously drought stricken Tayuan Brigade in Guanzhuang Commune where 11 of the brigade's 12 pump wells have gone dry and where people and animals face extreme hardships in getting drinking water. Together with the cadres and masses he studied actions to be taken. They sank a well in each of the two hamlets of Lincun and Xiaocai, which had a fair amount of ground water, and they erected steel pipes to solve people's and animals' drinking water problems and the problem of a source of water to be carried into the fields to dibble deeds on 1,000 mu. At Taitou Commune, Jinghai County CCP Committee Secretary Tong Zemin [0157 3419 3046] made the most of the fair amount of water lying not far below the surface locally by getting the masses to sink more than 800 hand pump wells and dug wells walled with bricks. Within a period of only 3 days, he got the masses to carry water to dibble seeds on more than 1,300 mu, and he also got the commune and brigades to put up the funds to buy 10 new spray irrigation apparatuses so as to expand the irrigated area by more than 4,000 mu. Leadership cadres in the western suburb and in Ninghe County uncovered and solved problems in cooperation with grassroots cadres and commune members, vigorously advancing progress in combating drought and doing spring planting.

In order to concentrate energies on the fight against drought, all suburbs cut back on the number of meetings and temporarily suspended regulations permitting cadres to rotate vacations. The suburbs and counties of Wuqing Baoshi, western suburb, and Tanggu set up commune cadre work position responsibility systems, and adopted methods of linking together garden team division of labor in fulfillment of grain and vegetable production norms and proportional distribution of profits from sideline occupations to solve the problem of a tendency to regard sideline occupations as superior to farming. In addition, all suburbs and counties did everything possible to reduce non-productive expenditures. More than 3.88 million yuan of local public funds was alloted to help communes and brigades in their struggle against drought, and the masses were aroused to chip in more than 11 million yuan to assure no hitches in the fight against drought to assure a wheat harvest and spring planting.

More than 900,000 people throughout the city are now engaged in the struggle against drought. Water is being hauled on carts, on poles by people, and on the backs of animals for the watering of 1.5 million of the municipality's more than 1.9 million mu of winter wheat, and a second watering of more than 880,000 mu as well. More than 2.4 million mu of field crops have been sown through fighting drought. This amounts to 60 percent of the task, and almost 400,000 mu was planted by dibbling seeds in the fight against drought.

YUNNAN SEEKS TO REPAIR COLD WEATHER CROP DAMAGE

Kunming YUNNAN RIBAO in Chinese 14 May 82 p 2

[Article: "Zhaotong Prefecture Fights Disaster to Win Bumper Harvest. Not Fearful of Difficulties Despite Drought, Prefecture Has Resown More Than 8,000 Rice Seedlings and Replanted More than 5,000 Mu of Corn"]

[Text] Following recurring natural disasters, the rural communes and brigades of Zhaotong Prefecture did not lower their heads or fear difficulties, but aroused cadres and masses to base themselves on a fight against disasters to win a bumper harvest. As of 25 April, 8,023 of the prefecture's 9,051 mu of rotting rice seedlings had been replanted, and an additional more than 2,300 mu of flue-cured tobacco seedlings sown.

Zhaotong Prefecture has had calamitous weather ever since April, temperatures remaining low for a fairly long time. Some counties had one hailstorm after another and damage from flooding and waterlogging, which caused serious damage to both crops sown in late autumn and early spring as well as to rape and tobacco seedlings, and to fruit trees. Serious rotting of rice and tobacco seedlings occurred, and a large amount of corn rotted. After the disaster, comrades in positions of responsibility in the Prefecture CCP and government administrative offices went separately to Suijiang, Weixin, Qiaojia, Daguan, Yanjin, Zhenxiong, Shuifu, Ludian, and Zhaotong counties to survey and gain an appreciation of the disaster situation. They called upon cadres and the masses throughout the prefecture to carry forward a great dauntless spirit of courage and tenacity in the face of the disaster, to overcome fears of difficulties and slackness, and to triumph over the disaster to do a good job of spring farming. Specifically, they took three actions as follows: 1. Growing of rice and tobacco seedlings. In order to assure the right season for transplanting, they intensified care of plots where the disaster and the rotting of seedlings had not been too serious and used every available means to grow sturdy seedlings. Fields in which losses were in excess of 80 percent were plowed under and resown. For resowing of rice seedlings, intermediate and early ripening varieties were used throughout. Insofar as possible plastic mulch was used to grow seedlings and hot, quick acting fertilizer was spread. Beginning now, organizational work for the transfer of seedlings from surplus areas to shortage areas is being done. 2. Attention to the season to hasten the pace of corn planting so as to avoid summer drought and autumn waterlogging. 3. Peasant households without the resources to solve hardships created by resowing and replanting following disasters plus disasters sustained to autumn sown crops were given appropriate relief by civil government departments. All counties in the prefecture responded to the Prefecture CCP Committee's call to active participation in the struggle against drought. As a result of efforts on the part of cadres and masses throughout Shuifu County, resowing of rotted seedlings has been entirely finished. Weixin County is now planting more than 130,000 mu of corn, and in order to assure full stands, in addition to increased fertilization at the time of sowing, they have promoted fine varieties, made sure to process seeds, and have done reasonably close planting. In addition 884 production teams have readied corn seedlings for prompt seedling replacement.

TITLE: "Accelerating the Development of Animal Husbandry"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 6, 5 Jun 82 pp 5-7

ABSTRACT: In the past, it was said that more animals more fertilizer, more fertilizer more grains, to explain the dialectic relationship between farming and animal husbandry. This is not sufficient to illuminate the importance of animal husbandry in the national economy, however. Animal husbandry products are required by departments of textiles, foods, leather-making, feather processing, chemistry, pharmaceuticals, and export trade. Just as Chairman Mao said: "An economy without animal husbandry is an incomplete national economy." The author urges that the position and function of animal husbandry should first be fully understood and acknowledged before related policies, scientific studies, and technological extension work are developed to promote and improve animal husbandry. Detailed measures to be adopted are offered.

TITLE: "Attend to the Work of Reserving and Managing the Capital Accumulated by the Collective Body"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 6, 5 Jun 82 pp 30-31

ABSTRACT: A survey was carried out in Feb-Mar 82 in Xuxian of Anhui Province for the purpose of understanding the condition of management of the originally accamulated capital and the condition of accumulation of new capital of the collective bodies after the adoption of the system of guaranteed production by households of production teams. The situation in Xuxian Prefecture is found by the survey team to be greatly improved, but new problems have also surfaced. For example, on the basis of the total value of products, the ratio of reserved common capital is lower. The paper suggests the following: (1) A percentage must be reserved from the production income for the depreciation of fixed and liquid assets which still belong to the collective body. (2) Concrete methods of managing the common capital reserve, the depreciation fund, and the loans (including seeds, chemical fertilizer, and cash) borrowed by the household for production from the common reserve. (3) There should be a definite and reasonable ratio (3-5 percent is too low) to be taken as a common reserve and the banks and credit unions should help the communes and brigades manage the funds properly.

TITLE: "Accelerate the Pace of Agricultural Development of the Region of the Huanghe-Huaihe Plain in Eastern Henan"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 6, 5 Jun 82 pp 40-41

ABSTRACT: The Huanghe-Huaihe Plain of eastern Henan is flat. The total area of 23 thousand km^2 has a thick layer of topsoil. The cultivated acreage is 22.2 million mu; with a population of 13.47 million, the per capita farm land is 1.8 mu. It is a base of wheat production of the province as well as one of the 4 cotton producing regions. After carrying out a survey of the region, the authors believe that its natural conditions of light, heat, and water are relatively superior, the potential for agricultural production is great, and the capital requirement for its development is not great. The following measures and procedures are suggested: (1) The first necessary item is afforestation. (2) Aridity and low organic matter content of soil should be taken care of by irrigation with water from Huanghe and enlarging the acreage of beans, which will help resolving the problem of firewood shortage as well; (3) Reconstructing the sandy fields; (4) All out development of animal husbandry; (5) Establishing bases of wheat, soybean, cotton, etc. in a suitable degree of concentration; (6) Raising the level of scientific cultivation.

ORG: Shanghai Cotton Spinning Plant No 7

TITLE: "Investigation Into the Quality of Shandong Cotton"

SOURCE: Shanghai FANGZHI XUEBAO [JOURNAL OF CHINA TEXTILE ENGINEERING ASSOCIATION] in Chinese Vol 3 No 4, 1982 pp 55-57

ABSTRACT: Shandong Cotton, Lumian No 1, is the high yield breed of 1980. After it was examined, accepted, and used by the cotton spinning plants, it was compared with unprocessed cotton produced in other regions. An investigation was carried out into its quality, its degree of maturity, and the reason for its low single fiber strength. Shandong Cotton is compared with 21 other raw cottons in terms of color, luster, fineness (m/g), maturity (coefficient), strength (g), breaking length (km), length of main body of fiber, evenness, and short staple. Aside from fiber whiteness, Shandong Cotton is generally half to one grade lower than the national cotton indices. The relationship between the number of days of growth of cotton bolls and such fiber properties as fineness, length of main fiber, single fiber strength, and coefficient of maturity is discussed. Analysis reveals that color absorption is the best with American Cotton and Hubei Cotton, mainly because their degree of maturity is better. Not only that the spinning plants have had the above problems with Shandong Cotton, it is also poor in terms of economic accounting, its only advantage of low foreign matter content notwithstanding. Its high yield in 1980 remains a matter to be congratulated. It should be possible to overcome the aforementioned problems.

ORG: Yunnan Provincial Cooperative Group For Comprehensive Prevention and Control Research of Cotton Fusarium Wilt and Verticillium Wilt

TITLE: "Summary of Research on the Comprehensive Prevention and Control of Cotton Fusarium Wilt and Verticillium Wilt in Yunnan Province"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3,25 May 82 pp 26-27

ABSTRACT: Cotton wilt is a destructive fungus disease, having been listed among the objects of inspection by the State. It had been discovered in Yunnan in scattered areas long ago but there was no spreading. After a large quantity of contaminated seeds were transferred into the province from Hubei in 1969-70, the diseases surfaced in 1970 and continued to spread rather fast after 1972. The yield dropped wherever the diseases touched. In Binchuan, it had dropped from the 72 jin/mu of 1966 to the 21 jin/mu of 1973, nearly the level at the time of the liberation. The cooperative research group was organized in 1972 to launch large acreage pilot fields to demonstrate comprehensive prevention and control measures centering upon the use of disease resistant breeds. The unit yield of the pilot fields rose from the 46 jin of 1975 to the 92.57 jin of 1980. In 1975-76, a general and sample survey was carried out in areas totaling 116,441.54 mu, of which the diseases were found to affect 95,392.59 mu, amounting to 81.92 percent. The number of diseased plants may be reduced from about 50 percent to 12-20.7 percent, when the cotton field is rotated with paddy rice crops for 1-2 years and down to 0.3-3 percent after 3 years of crop rotation with paddy rice.

ORG: Shanghai Municipal Cotton High Yield Culture Cooperative Group

TITLE: "Potential for Yield Increase Examined From the Viewpoint of the Yield Structure of Cotton"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 6, 5 Dec 81 pp 12-13, 19

ABSTRACT: The yield structure of cotton includes the number of bolls per mu, the boll weight, and the ginning turnout. There is a mutually dependent and mutually restricting relationship among the 3 factors, however. When the degree of effect of the 3 factors on the yield is clarified, the major direction of future efforts may be more correctly determined for the purpose of developing the yield increase potential. An experiment was carried out jointly by the Shanghai Municipal Academy of Agricultural Sciences, Shanghai County Institute of Agricultural Sciences, and Chongming Institute of Agricultural Sciences in 8 plots. Statistical analysis of the resulting yield, which coincides with the result of actual production in a large extent, reveals that when the breed is not changed, the variation of ginning turnout from year to year does not change the yield regularly because the variation is often the result of the weight of some defective seeds. The number of bolls per mu is found to vary less for transplanted cotton, compared with direct seeded cotton, while there is a greater variation in weight with plants transplanted into wheat mounds than those transplanted after the wheat harvest. Aside from

[continuation of SHANGHAI NONGYE KEJI No 6, 1981 pp 12-13, 19]

conditions of the weather and the management of water and fertilizer, the authors believe the one obvious problem at present is the previous crop. If the acreage of late maturing crops before the cotton crop continues to increase, the cotton will necessarily be late flourishing, the bolls be light in weight, and the yield low and unstable. In large area production, the number of bolls per mu is found to fluctuate a great deal. The paper concludes that the ratio of cotton acreage in fields of late maturing previous crops must be reduced so as to maximize the use of effective boll formation stage. While the system of cultivating seedlings for transplanting is being developed, the area of early maturing previous crops must be guaranteed for cotton culture for the purpose of developing fully the yield increase potential of cotton.

TITLE: "Effect of Seeding Time on the Growth and Development and the Yield Structure of Millet"

SOURCE: Dalian LIAONING NONGYE KEXUE [LIAONING AGRICULTURAL SCIENCES] in Chinese No 2, 15 Apr 82 pp 11-17

ABSTRACT: For the purpose of finding the suitable millet seeding time in Shenyang and Tieling regions, the author and colleagues experimented with seeding it on 15 Apr, 25 Apr, 5 May, 15 May, and 25 May to observe the morphology of the plants and to carry out growth and quantitative analyses. The experiment was repeated for 2 years from 1980-81. The results of the experiment indicate that the suitable seeding time in these regions is the period from 15 Apr to 5 May, with the days around the 25th of Apr the best of all. Moreover, these experiments also help clarify the distribution process of the assimilation products of millet of different seeding times and the physiological basis of the yield formation. The interrelationship between the growth and development principle of millet and the internal and external factors is thus understood. Results of the experiments are analyzed and reported.

TITLE: "A General Discourse of Trace Element Fertilizers"

SOURCE: Dalian LIAONING NONGYE KEXUE [LIAONING AGRICULTURAL SCIENCES] in Chinese No 2, 15 Apr 82 pp 34-36

ABSTRACT: In the growth and development process, crops need a great deal of carbon, hydrogen, oxygen, nitrogen, phosphorus, and potassium and the quantity of molybdenum, boron, zinc, manganese, copper, etc. needed by the crops is very little and these are commonly called trace elements. Generally, soils are not deficient in trace elements but their contents in soils vary as much as 100-fold. Alkaline soils may easily be deficient in boron, zinc, copper, etc. and in acid soils, effective molybdenum often precipitates under the action of the free iron and lead in the soil. Moreover, when the crop repeating index is increased, the phenonmenon of trace element deficiency may also appear. These trace elements have important biological function in the body of animals, plants, and microbes; they are components or activators of many enzymes in plant bodies and they affect mainly the metabolism of the plants. In China, experiments with trace element fertilizers have had a history of only 20+ years. In 1978, about 2,000 tons were applied to 25-30 million mu of cropland, amounting to 1.7-2 percent of the total acreage of the country. The application and function of molybdenum, boron, zinc, manganese, copper fertilizers in China are briefly and separately reported. The paper also discusses briefly signs of soil trace element deficiency and the danger of overabundance of trace elements.

TITLE: "A Proposal for the Development of Yams in Chaoyang Prefecture"

SOURCE: Dalian LIAONING NONGYE KEXUE [LIAONING AGRICULTURAL SCIENCES] in Chinese No 2, 15 Apr 82 pp 40-43

ABSTRACT: In Chaoyang Prefecture, the yield of crops is unstable. In 1979, the year of the highest yield in the 30 years since the liberation, the average yield was 412 jin/mu but it dropped to 114 jin/mu in 1981, the year of the second to the worst harvest in these 30 years. The chief problem is aridity and the solution is soil and water conservation with emphasis on afforestation and grassland culture to establish a favorable ecological system and thus reinforcing men's ability of controlling nature. On the other hand, different crops react differently to aridity and soil fertility. In thin soils with no fertilizer, the yield of sweet potato or yams is higher than corn and under the condition of high fertility, the reverse is the case. Of the 7.8 million mu of cropland in Chaoyang Prefecture, more than 70 percent are mountain slope thin soils, which are suitable for yams. For the purpose of reasonable utilization of land to improve the economic benefits, it is absolutely necessary to restore and further develop yam production. The yield increase results of yam crops, their economic benefits, their action in improving the ecological environment, and their drought resistant and poor soil tolerance are described in some detail. The author urges the establishment of experienced technical teams and the extension of technical knowledge through broadcasting, journals, and newspaper articles to reestablish and develop a sweet potato culture in the prefecture, which the masses were forced to abandon during the decade of turmoils.

Insecticide Characteristics

AUTHOR: WU Wenjun [0702 2429 0689]

ORG: Department of Plant Protection, Northwest College of Agriculture

TITLE: "Mechanism and Toxicological Characteristics of Carbamate Insecticides"

SOURCE: Beijing KUNCHONG ZHISHI [ENTOMOLOGICAL KNOWLEDGE] in Chinese Vol 19 No 2, Mar 82 pp 40-42

ABSTRACT: It is generally believed that carbamate insecticides suppress the acetyl cholesterol enzyme (AChE) in the body of the insect but for a long time, there have been 2 different views on this supressing action: By combining with the AChE to produce a stable compound and thus causing the AChE to lose its activity, or by a chemical reaction with the AChE to produce aminoformacyl enzyme and thus suppressing the AChE activity. Through analyses of the chemical reactions, the paper demonstrates that the shortcoming of the first viewpoint is the denial of the existence of the aminoformacyl reaction; that of the second is to equate carbamate insecticides with organophosphatide insecticides. Both are onesided. Through a detailed explanation of the 5 toxicological characteristics of carbamate insecticides, the paper further explains that the carbamate insecticides depend mainly on their very small K_d value while the organophosphatide insecticides depend upon their relatively large K_2 value and relatively small K_3 value. The antidote for the latter is; therefore, not effective for the former, when vertebrate animals are poisoned by either of the two.

ORG: Grain Cultivation Office, Institute of Crops, Shanghai Municipal Academy of Agricultural Sciences; Technology Extension Station, Municipal Bureau of Agriculture

TITLE: "Opinions Concerning the Late Crop Rice Cultivation Technology in 1982"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 1-3

ABSTRACT: In the suburbs of Shanghai, there are 2 million mu of late rice crop, amounting to 80 percent of the total autumn grain acreage. The yield has never been stable, averaging 599.4 ± 85.8 jin, a variation coefficient as high as 14.3 percent. The yield of the 2 recent years was extremely low, only 362 jin in 1980. Based upon the experience of some high yield units and related research data of the academy, the following suggestions are offered to change the low and unstable yield condition: (1) Older and stronger seedlings should be cultivated; (2) Hurry to transplant on 2-14 Aug because a yield reduction of 23 jin may result for every one day of delay beyond this period; (3) Transplanting quality should be guaranteed through satisfactory land leveling, basic fertilizer application, and reasonable density; (4) Carrying out scientific management of fertilizer and water as well as pest and disease control measures. Details are discussed under the above categories.

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 3-5

ABSTRACT: Several years ago, the authors carried out some surveys and studies concerning the quality of late rice seedlings in a dual crop system. Results of the research are summarized in the paper: (1) An important factor affecting the quality of seedlings is seeding density, mainly in terms of the dry weight and the N, P, K, sugar + starch contents of the seedlings; (2) Management of fertilizer and water, emphasizing the promoting as well as controlling function of water and fertilizer; (3) Applying flowing water for irrigation to reduce the water temperature 1-2°C to combat the hot weather condition and to improve ventilation of the seedbed.

TITLE: "Investigation Into Problems Relating to Greenhouse Culture of Rice Seedlings"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 6-7

ABSTRACT: Several years of experiment indicates that when rice seedlings are cultivated in the greenhouse the yield is basically the same as that of regular seedbed cultivation but some seeds, the seedbed, and some labor may be saved. The greenhouse requires a great deal of capital investment and the ripening time of the rice crop may be delayed, however. In order to resolve the problem of capital investment, seedling trays have been created to maximize the use of greenhouse space, plastic tents may be used for vernalization, some costly tools may be omitted and replaced with manual labor. The greenhouse is used only 3-4 months a year to cultivate early rice seedlings; therefore, in order to raise its benefits, measures should be adopted to cultivate edible fungi, vegetables, decorative plants, etc. during the remaining months of the year for comprehensive utilization and fast return of capital.

TITLE: "Preliminary Investigation Into the Yield Increase Effect of the Technique of Covering the Ground Surface of Cotton Field With Plastic Film"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 16-18

ABSTRACT: Covering the ground surface of cotton fields with plastic film is known to have the effects of raising the temperature, conserving moisture, and promoting decomposition of soil nutrients. The technique has been gradually extended in the north where the frostfree period is short, the temperature is low, and the rainfall is sparse. Obvious yield increase effects have been demonstrated there. In 1981, the authors carried out a small area experiment with this technique in the experimental farm of the academy to study its yield increase potential and economic benefits in the region of Shanghai. The following results are observed: (1) As the cotton seeding or transplanting time is delayed, the yield increase effect of the technique becomes more obvious; (2) The cost of the plastic film is 36 yuan/mu and the income of the yield increase is only 28 yuan. It may appear that the technique does not pay, but such processes as hoeing, weeding, banking with soil, and fertilizer application are all omitted to cut the labor by 2/3. (3) Effect of the technique during a wet year remains to be studied further.

ORG: Blast of Rice Group, Institute of Plant Protection, Shanghai Academy of Agricultural Sciences

TITLE: "Analysis of Causes of Blast Epidemics in the Suburbs"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 23-25

ABSTRACT: In the region of Shanghai blast of rice affects mainly the neck of the spikes, occurring from the heading blooming stage to the starch filling stage. According to the 1973-80 statistics of the municipal Plant Protection Station, the affected acreage totals 9.123 million mu in these 9 years to cause a loss of rice grains of 20.561 billion jin. The paper analyzes the causes as follows: (1) Weak blast resistance of the late rice breeds; (2) Damaging weather in favor of blast epidemics; (3) Improper cultivation measures, including the quantity of nitrogen fertilizer inducing an imbalance of carbon-nitrogen ratio in the plant tissue, prolonged deep water level causing the soil to be deficient of air and anaerobic microbes to produce such toxic substances as hydrogen sulfide to ruin the root system of the rice plant and weaken its resistance. Concrete measures are suggested to overcome the above problems and to control blast epidemics.

TITLE: "A Research on Several Feeding Techniques to Raise the Ratio of Lean Meat of the Hybrid Swine, Du x Shang"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 5 Jun 82 pp 34-35, 22

ABSTRACT: On 11 Jan - 11 Apr 1981 and 18 Jun - 12 Sep 1981, 2 experiments were carried out to compare the lean meat rate of the hybrid, Du x Shang of 3 feeding methods: limited quantity dry feed, limited quantity soupy feed, and dry feed on demand. Results of both experiments indicate that the lean meat rate is the highest when the porkers are fed with limited quantity of dry feed, being 30.45 and 30.76 percent lean meat. It is lower with dry feed on demand, being 29.61 and 29.93 percent. With limited quantity soupy feed, the rate for the first experiment is 30.55 percent, the second 29.86 percent. With the limited quantity dry feed, the butcher rate is slightly lower than the limited quantity soupy feed group, however. The lean meat rate of these 2 experiments is lower than the 2 experiments carried out previously (59.81 and 59.74 percent) because this time the period after weaning and before the experiment is lengthened. This just goes to show that in order to obtain the highest lean meat rate, feeding should begin when the porker weighs about 20 kg.

TITLE: "Reasonable Utilization of the Tillering Vigor of Hybrid Rice In View of the Tillering, Spike Formation, and Fruiting Characteristics of Nanyou No 6"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 6, Jun 82 pp 1-5

ABSTRACT: An obvious characteristic in the yield structure of hybrid rice is the high ratio of tiller spikes, amounting to about 80-90 percent of total and about 30-50 percent higher than regular breeds. Under the condition of low density, at the age of 16 leaves on the main stem, Nanyou No 6 is observed to tiller in every node except the elongated node of the main stem. The number of tillers of a single stalk is generally 15-20, appearing in various orders, locations, and times. Their rate of spike formation and spike quality vary with obvious regularity. For the purpose of acquiring the highest number of effective spikes, the ideal situation is to have 5-6 tillers from the first tillering phase and 3-4 from the second phase. Those of the third phase are generally not effective tillers. In order to achieve this situation, the seedling should have 3 large tillers at the transplanting time. The observational data of the tillering characteristic of Nanyou No 6 and a detailed cultivation procedure for obtaining the optimal number and type of tillers in order to produce the highest number of effective spikes are given.

TITLE: "Research on the Multiple-crop Rotation System of Rice Paddies: I.The Overall Benefits of Multiple Crop Rotation System"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 6, Jun 82 pp 12-15

ABSTRACT: Since the early 50's, there have been several reforms of the cropping system of rice paddies. By the early 70's, a system of 2 crops of rice and one crop of green manure was formed to produce yield increases for rice but prolonged continuous cropping led to deterioration of soil physical-chemical properties and diseases, pests, and weeds multiplied. In the winter of 1977, a project was launched to experiment with a comprehensive system of crop rotation. Results of 4 years demonstrate that this system has brought an increase of 30.78 percent in terms of total farm product value, an increase of food grain from 620 to 710 jin per person, an increase of 31.1 percent in grain sales to the State, and an increase of soil organic matter from 1.7882 to 2.0597 percent. The system involves rotating crops in the following order: (1) lima bean - rice - rice; (2) wheat - bean- green manure - rice; (3) green manure- rice - rice; (4) oil crop - rice - beans; (5) oil crop - rice - rice; (6) wheat - beans - cotton. Conditions of utilization of light and heat, the conversion rate of effective solar radiation, nitrogen and organic matter contents of soil under this system of crop rotation are analyzed in some detail.

TITLE: "Selection Breeding and Utilization of Topcross Corn to Adapt to the Special Ecological Condition of High Mountains"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 6, Jun 82 pp 15-16, 5

ABSTRACT: In the alpine region of Enshi, the elevation is 1,400-1,800 m, the temperature is low, the humidity is high, clouds and fog are unceasing, sunlight is scarce, and the frostfree period is very short. With these unfavorable factors the corn yield has been very low all the time. In recent years, many breeds have been introduced from the outside and several types of hybrids have been tried. Most of these have a growth and development period too long for the region and cannot withstand the low temperature. Since 1979, the Corn Research Group of Enshi School of Agriculture has carried out a project of comparing and testing 232 hybrid combinations and 28 superior ones were identified in the first year. Of these 16 are topcrosses. One of these, Chunmuying Xiaozihuang x R-64, was picked for demonstrations in many areas of a range of elevation of 1,400-1,800 m. Its yield was, in the 2 years of 1980 and 81, 500-700 jin/mu, 21.1-98.7 percent higher than the control which was a local hybrid, Xiaoying. Characteristics of this topcross and the reasons for its superior yield are discussed.

TITLE: "A Study on the Cultivation Characteristics of Owan No 5: I. Yield and Growth and Development Characteristics of Owan No 5"

SOURCE: Wuhan Hubei NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 5, May 82 pp 1-4

ABSTRACT: Owan No 5 is a new late Geng rice bred out by the institute; it has been extended to more than 1 million mu within the province and the acreage is being continuously enlarged. For the purpose of promoting its yield increase effect in large acreage production, the paper introduces its agronomical characteristics, based upon the high yield cultivation and experimental data of 1981. When it was seeded on 20 Jun and transplanted on 23 Jul, in a density of 3 x 5 cun of basically 238 thousand seedlings/mu, there were 369.2 thousand spikes/mu on the average, at a spike formation rate of 69 percent; 52.2 grains/spike were obtained, at a fruiting rate of 84.1 percent. The grain test weight was 21.82 g/1000 grains. The final yield was 840.2 jin/mu at a grain to straw ratio of 0.91 : 1. An experiment for determining the effects of different seeding and transplanting dates (15, 20, 25, and 30 Jun) on its growth and development and its yield, and the reaction of this breed to temperature and light are also reported. Seeding it properly late for early transplanting of young seedlings is recommended and this characteristic is considered favorable for its extension in large areas.

TITLE: "Economic Effects and Key Techniques of Dry Culture of Hybrid Rice Seedlings"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 5, May 82 pp 6-9

ABSTRACT: When hybrid rice is used as the second late rice crop, it is easier to obtain high yield. It matures early and is suitable for winter seeding. With the triple-crop paddy system of Huanggang Prefecture, there is a large proportion of slow ripening early rice, however, while hybrid late rice requires an early ripening previous crop because the present hybrids all belong to the Xian type, which is very sensitive to low temperature. Results of many years of experiments at the institute indicate that seedlings grown in a dry seedbed have higher nitrogen and starch contents to cause their nutritional growth period to be prolonged and their resistance to adverse environment strengthened. There is also a reduction of labor intensity. When these upland seedlings are transplanted, they grow vigorously to form large nutritional bodies in a short time. The soil of the dry seedbed must not be too tight and must have a proper amount of moisture to allow the seedlings to be pulled easily from the soil before transplanting.

COMMENTATOR CALLS FOR QUALITY CENSUS TAKING

Beijing ZHONGGUO NONGMIN BAO in Chinese 10 Jun 82 p 1

[Article by commentator: "Assure Quality in Rural Census"]

[Text] Currently preparatory work for a census in China's farflung rural village is feverishly under way. An overwhelming majority of areas have run census pilot projects to gain valuable experiences; the work of commune training census personnel has been substantially completed in most parts of the country; propaganda work about the census is being pervasively launched with many areas having made lantern slides, trained propaganda personnel, and conducted a census of middle school and primary school students. Overall the work has progressed smoothly and achievements have been very great.

However, we should also clearheadedly realize the considerable difficulties in conducting a rural census. This is because the cultural level of China's rural population is lower than that of cities, so completing the recording of as many as 19 census items must inevitably mean difficulties will be somewhat greater and that questions must inevitably be somewhat more numerous. In addition, the rural household registration system has not been sufficiently well perfected, so the foundation for census work is relatively poor. In rural communes and brigades, and particularly in the farflung border regions, people's abodes are very scattered and the migratory population is fairly great, making for inconveniences and increasing difficulties in taking the census.

We recognize the difficulties and want to overcome the difficulties to do a good job. Ours is a country of 1 billion population of whom 800 million are peasants. Quality of the rural census will decide the quality of the census for the country as a whole and will bear on whether this national census is a success or a failure. This has wide ramifications, so we must be determined to do a good job of it.

Most important in doing the rural census well is to do conscientious and extremely meticulous work. There can be not the slightest bit of perfunctory manner or carelessness. Commune and brigade leadership comrades must diligently and exceedingly meticulously organize. They cannot push this matter off on accountants or sit in an office, relying on "seems natural" to fill out forms and consider the matter finished. Instead, they must carry it out household by household and person by person. The broad masses of census takers must brave all hardships, not fear inconvenience, and fill out every single census registration form in scrupulous detail; they must postively assure no duplications, no omissions, and no errors. The broad masses of peasants should also make a conscious contribution to the census work, conscientiously and responsibly answering factually each individual census item.

China's peasants possess very high political consciousness. If only we do wide and pervasive propaganda work to mobilize them, explaining the reasons clearly to everybody, the broad masses of peasants will certainly actively cooperate and do a good job, and the rural census can certainly be successfully completed with high quality.

RULES GOVERNING COMMUNE DEALINGS IN AGRICULTURAL PRODUCTS EXPLAINED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 5 May 82 p 41

[Article by People's Commune Enterprises Administration, Ministry of Agriculture: "May Commune and Brigade Enterprises Engage in Business and Processing Industries?"]

> [Editor's note: Recently some letters recevied from readers have focused on two problems about the scope of dealings by commune and brigade enterprises, People's Commune Enterprises Administration of the Ministry of Agriculture replies to which are printed below.]

[Text] Question: May the supply and marketing organizations of people's commune enterprises purchase and market commodities?

Answer: Commune and brigade enterprises are an integrated economy under rural people's commune collective ownership and include agriculture, industry, transportation, construction, and commerce. In 1980, their output value amounted to 12 percent of the national gross output value from industry and agriculture, making them a major integral part of the national economy. In order to serve commune member production and livelihood, in accordance with the spirit of the CCP Central Committee and State Council notice titled, "Need for Finding Multiple Ways of Opening and Developing Flow Channels," they have put into effect commodity flow channels of "multiple economic ingredients, diverse forms of operations, numerous channels, and few links." In rural villages, apart from mainstream supply and marketing cooperative mainstream channels, in recent years all jurisdictions have test run and developed, in a planned way, commune and brigade collective businesses such as trade warehouses, joint supply and marketing management departments, and integrated agricultural, industrial, and commercial enterprises, etc. to form another supplemental flow channel. The appearance of this flow channel has been a convenience for the masses, has enlivened the rural economy, and has advanced development of commodity production. Consequently, the "Summary of the Minutes of the National Conference on Rural Work," which was approved and forwarded by the CCP Central Committee in January 1982, both affirmed and required that commercial departments at all levels actively support and guide commune and brigade development of sales promotion and procurement activities as a major task for themselves. All levels of planning, public finance, material, and transportation departments should accommodate commune and brigade collective businesses, commune and brigade enterprises, and integrated agricultural, industrial, and commercial enterprises in setting up accounts. After rural businesses have put multiple channels into effect, local people's governments should strengthen leadership, prescribe the scope of their activities, and do a good job in coordination, channeling guidance, and management." In accordance with a series of Central Committee and State Council regulations, the scope of one category of commune and brigade commercial operations is procurement of the various raw materials and supplementary materials needed by commune and brigade industries. These include the following: agricultural products dealings outside state procurement base figures that communes and brigades may handle as they see fit; second is raw materials newly developed by commune and brigade enterprises; third is exchange and cooperation internally on raw and processed materials that commune and brigade enterprises produce; fourth is procurement of agricultural products remaining following fulfillment of state distribution and procurement quotas; and fifth is receipt of materials for processing from foreign traders and from outside the country. A second category is marketing operations including the following: one is marketing of goods produced by commune and brigade enterprises; second is organization for production of goods for use in the export trade; third is dealings in state owned industrial and commercial wholesale commodities; fourth is serving as a purchasing and sales agent on commission from state industries or businesses; fifth is helping communes, brigades and commune members sell agricultural products not purchased by the state. Development of all these operations must be done under guidance of state plan and with respect for national laws. There positively can be no disregard of state plan, jacking up of prices, or pre-emptive buying of commodities.

Question: Are commune and brigade enterprises permitted to deal in the processing of second and third category farm products?

Answer: Permitting communes and brigades to process farm products themselves has consistently been a policy of the state. As early as 1951 in "Decisions on Mutual Assistance and Cooperation in Agricultural Production," the CCP Central Committee proposed development by agricultural cooperatives of agricultural product processing industries. In September 1956 the "Directive on Strengthening of Production Leadership and Building the Organization of Agricultural Production Cooperatives" issued by the CCP Central Committee and the State Council pointed out the following: Agricultural sideline product processing industries should not be overly concentrated in cities. Overconcentration makes it impossible to satisfy peasant needs for livestock feeds and fertilizers and is, at the same time, a reason for the decline of rural sideline occupation production. Consequently, processing industries for the grinding of rice, the ginning of cotton, and the pressing of oil should not be overly concentrated in cities. Except for the supply of raw materials needed by existing processing plants, all other agricultural products should, insofar as possible, be processed by local villages and towns or by agricultural cooperatives." The "Decisions on Various Problems in Hastening Development of Agriculture" of the 11th Party Central Committee in 1979 also pointed out that "in accordance with the principle of economic cooperation, any farm products that lend themselves to rural processing should gradually come to be processed by commune and brigade enterprises." State Council Document No 170 issued in 1979 ruled a need to "make efforts to develop agricultural commodity processing industries." State Council Document No 77 of 1981 further stipulated that "henceforth whenever there is a surplus of processing capacity in state enterprises, communes and brigades are not to run any more similar enterprises or expand processing capacity. For all processing using agricultural sideline products as raw materials that can be done in rural villages, the state will not further build new plants in cities or expand processing capacity, but should act on the principle of economic cooperation to support development of collectively owned processing industries." The most recently published "Summary of the Minutes of the National Conference on Rural Work" approved and sent forward by the Central Committee also clearly pointed out that "provided planned state quotas are assured fulfillment, there should be active development of on-site processing concentration, and overall use of agricultural sideline products." "Except for agricultural product processing industries that rural communes and brigades want to continue to develop, either commercial units may themselves process purchased farm products, process them jointly with communes and brigades, or commission commune members to process them in their homes." In order to correctly handle concurrent concern for the welfare of the state and collectives, the "Minutes" noted that "the agricultural economy is a major integral part of the national economy, with the planned economy being paramount and market regulation being ancillary. For grain and edible oils, a policy of centralized procurement and centralized marketing should continue to be followed. For assigned procurement of second category agricultural products, equitable base figures should be set and maintained without change for several years. In the case of goods for which base figures cannot be readily set, equitable procurement and retention proportions should also be set. Portions not included in base figures may also be purchased by the state, or the state may purchase a proportional portion of some. In some cases all of them may be handled at the discretion of communes, brigades, and the peasants "for processing and marketing." With regard to commune and brigade enterprise dealings in second and third category agricultural commodities, State Council Document No 3 of 1981, "Directive on Strengthening of Marketing Management, and Cracking Down on Profiteering, Speculation, and Smuggling" clearly stated that "rural commune and brigade collectives, may traffic in goods from their own commune and brigade or from nearby communes and brigades that are surplus to fulfillment of state procurement quotas and the carrying out of negotiated procurement contracts, or are category 2 and 3 agricultural sideline products not purchased by the state. They are not allowed to traffic in category 1 agricultural sideline products."

COMMENTATOR STRESSES DISTRIBUTION OF SUMMER EARNINGS

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinse No 6, 1982 pp 28, 42

[Article by commentator: "Give Attention to Distribution of Summer Earnings To Promote Production for the Year as a Whole"]

[Text] The job of distributing summer earnings has already begun in rural communes and brigades. Doing a good job of summer earnings distributions this year is a formidable responsibility of major significance.

Summer earnings distributions this year differ from previously, and this situation should be clearly realized. First of all, as a result of the practice of different forms of production responsibility systems, diverse ways of figuring compensation and manifold accounting methods have come into being. Contracts contain many different provisions, and rewards and penalties are of numerous kinds for a new situation. Assiduous honoring of all forms of agreements is a major task in this year's summer earnings distribution work: agreements are to be treated seriously and doing things perfunctorily is to be strictly guarded against. For example, production teams practicing production responsibility systems of specialized contracting, linking output to teams, individual households or individual workers must diligently act as agreements require, strengthen organizational leadership work and, in the course of harvesting and threshing, should guard against mix-ups at the threshing ground, mixing up production from different sources, mixing up accounts, or mixing up workers. The masses say, "accounts should be kept meticulously in accordance with agreements"; whatever agreements were stipulated at the outset should be lived up to with no saying one thing at the beginning of the year only to change it in the summer. This is a matter that bears on the credibility of responsibility systems and involves the personal interests of a myriad of commune member households that must be handled well so the masses will be satisfied. Communes and brigades practicing the fixing of output quotas on a household basis and peasant household assumption of full responsibility for task completion, and particularly those practicing the assumption of full responsibility by individual households, should inspect how well contracts are being fulfilled in distribution of summer earnings. They should take firmly in hand fulfillment of state purchase quotas, and they should clearly explain to everyone how withholdings are to be used. The masses speak well when they say, "Once accounts are closely figured, sharing is done as it should be; and when intended uses are clearly explained, withholdings are made as they should be." Commune members must be taught that when a bumper harvest has been reaped, the collective and the state are not to be forgotten, and that concurrent concern for the welfare of the state, the collective, and individuals should be regarded as a duty that each household of contracting commune members must carry out with no thinking of only one party or of only two parties, but rather the need for concurrent concern for the three.

In making summer earnings distributions, fiscal reorganization work should also be inspected to determine whether collective property that should have been inventoried and recorded has, in fact, been inventoried and recorded, whether credits and debts have been checked and put into effect, whether collective withholdings and depreciation expenses have been deducted, whether a fiscal system has been established, etc. These tasks should be regarded as major ingredients in the safeguarding of collective property and consolidation of the collective economy.

This year's summer earnings distribution work has yet another feature. Because during the time of fall sowing last year temperatures were low in the north and the south had much rain, which hurt quality of fall sowing and wheat seedling growth, plus damage caused by drought in some areas, the size of the summer harvest differs from one place to another, individual areas having bumper, ordinary, or lean harvests. This situation requires intensified unified planning with due consideration for all concerned and equitable arrangements. Bumper harvest areas have to carry forward the spirit of love for the country and love for the collective to make a greater contribution to the country and to the collective. Places having ordinary harvests should assure fulfillment of state quotas and proper collective withholdings should be made. Communes and brigades with lean harvests must provide for the livelihood of commune members first of all, and show concurrent concern for the welfare of the three after this has been done. It is also necessary to consider the customary living standards of commune members and proportionally watch summer grain with autumn grain. Places having a large ratio of summer grain production should, in addition to providing for commune members' livelihoods, do everything possible to better fulfill state purchase quotas.

Leaders at all levels, particularly county and commune leaders, must devote their energies to doing a good job of this year's summer earnings distribution work. They should particularly combine summer earnings distributions, inspection of how well Central Committee Document No 1 has been carried out, and the actual state of improvements in responsibility systems. All problems requiring solution should be solved and experiences should be summarized for steady progress. As a result of summer earnings distributions, the zeal of commune members will be encouraged and greater efforts devoted to production for the year as a whole to achieve a situation in which the summer provides impetus for the fall, for ceaseless and unremitting work to win a good harvest in agriculture for the year as a whole.

NEED FOR IMPROVED EFFECTIVENESS OF WATER PROJECTS STRESSED

Beijing NONGCUN GONGZOU TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 1982 p 16

[Article by Luo Zicheng [7482 1311 4453]: "Strive To Increase Water Conservancy Project Economic Benefits"]

[Text] Improvement of management to increase economic benefits from existing farmland water conservancy projects is one major aspect of improvement in benefits from the agricultural economy today.

Agricultural production is biological production, and it is inseparable from the restraints and influences of light, heat, water, soil, and climate. China frequently experiences drought and flood disasters. If water conservancy projects are effectively handled, not only do farmlands benefit with water, but drought and flooding can be resisted. During the past 3 years, the agricultural economy has burgeoned, and a determining factor has been the correctness of the line and policies that have followed from the Third Plenary Session of the 11th Party Central Committee, which have aroused the enthusiasm of hundreds of millions of peasants. In addition, this burgeoning is inseparable from the vigorous support given to agriculture by the state over a long period of time for the building of farmland water conservancy projects on a fairly large scale.

Now, in this period of national economic readjustment, the state is experiencing certain hardships in public funding and, for the moment, the peasants also lack the resources to build new large scale water conservancy projects. Better use of the role of existing water conservancy projects possesses major practical significance. Leadership departments concerned have put forward guiding programs centering on the strengthening of management and increasing benefits. We must pool our efforts and wisdom to manage existing water conservancy projects well, and to make better use of the benefits they provide to create further favorable conditions for steady increases in output.

For a long time water conservancy project management has been rather antiquated. This has been manifested in the following: production with calculation of costs, lack of standards pertaining to earnings and expenses, no fixing of responsibility for work, no concern about benefits from the work that is done, and egalitarian "eating out of a large common pot" no matter whether one works much or little, well or badly, or works or does not work. In many places projects have fallen into disrepair or have been damaged, and some project systems have not been equipped to form a coherent whole. Some management conditions are poor. There has been a general lack of sources for funds making difficult necessary maintenance and repairs. Grassroots units at many water conservancy projects have been hard pressed even to maintain simple reproduction. Consequently, strengthening of farmland water conservancy project management is an urgent and important task.

The nub of improved management is the building of various forms of economic responsibility systems. Results of experiences at pilot project units in various places in Sichuan Province have been very good. They instituted centralized management, individual unit (or individual segment) accounting, specialized contracting, and fixing of responsibility on individuals, linking remuneration to output and benefits provided. A change was made from the overcentralization of individual rights, water rights, and property rights to their transfer to a lower level. Once grassroots management units had the right of self-determination, management personnel, staff and worker, and commune member enthusiasm was aroused. Various production, economic, and technical norms were also fairly readily implemented for fulfillment and overfulfillment of production quotas, which increased enterprise earnings and expanded and increased project benefits. Many pilot project units made a change for the long standing losses of the past to self-sufficiency or substantial self-sufficiency for their own expenses, and some even showed a profit.

In the strengthening of water conservancy project management, attention should be given to all-around operations, the development of the raising of fish, generation of electricity, growing of cotton, raising of poultry, afforestation, and tourism in a change from the former way of doing things of "looking after dams and guarding reservoirs, releasing water and maintaining ditches." In order to make full use of local area and local unit natural resources, a change has to be made away from the former reliance on the state to provide expenses, or just collecting small water fees, to the broadening into diverse sources for funds. The form of operations is also to be managed solely by water conservation units in gradual development in integrated operations managed by project areas, irrigation areas, reservoir areas and surrounding communes and brigades. As a result of consultations, some places may jointly operate small hydropower stations, branch companies for aquatic products, and jointly operated forest enterprises, etc., on a basis of voluntary participation and mutual benefit. Such all-around joint operations cement relationships between project management units and the surrounding masses. They broaden financial resources, increase funds for repairs and maintenance, promote project safety, and improve project benfits. They are advantageous for the state, collectives, and the masses.

Today the effectiveness coefficient for water used in irrigation in China is about 0.4. For some wetlands the volume of water used for irrigation amounts to 1,500 cubic meters; for drylands it amounts to as much as 800 cubic meters, more than double the normal quotas. In many areas, large amounts of water are used in flood irrigation and irrigation by channeling water along furrows, causing abandonment or recession of water, which both seriously wastes water resources and causes soil salinization and alkalinization. Consequently use of water must adhere to sensible fixed quotas and the strengthening of scientific and technical guidance on use of water. Furthermore, some readjustment of overly low water prices has to be made, fees being collected per cubic meter, with graduated increases in rates for consumption in excess of quotas.

Strengthening of water conservancy project management to increase benefits also requires steady strengthening and improvement of project quality, increased capabilities for guarding against floods and draining waterlogging, and improved project standards to assure project safety, particularly the safety of dangerous dikes on dangerous reservoirs. For the small number of projects on which construction continues, quality must be guaranteed so that work on them will be promptly completed and they can go into production.

FARMLAND WATER CONSERVANCY RESPONSIBILITY SYSTEM EXPLAINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 6 Jun 82 p 1

[Interview with Qian Zhengying [6929 29735391], minister of Water Conservancy and Power by ZHONGGUO NONGMIN BAO reporter: "Enhance Farmland Water Conservancy Responsibility Systems to Make Full Use of Existing Project Benefits; date and place not specified]

[Text] Following institution of agricultural production responsibility systems, how should farmland water conservancy work be changed to meet the needs of the developing situation? Recently a reporter from this newspaper called on Water Conservancy and Electric Power Minister Qian Zhengying to ask this question.

Question 1: How has it been possible to get fairly good harvests during the past several years despite the occurrence of serious natural disasters in many of the country's agricultural production areas?

Answer: The basic reason it has been possible to reap fairly good harvests despite the rather frequent incidence of droughts and floods in China during the past several years has been institution of agricultural production responsibility systems that have aroused the enthusiasm for production of the broad masses of the peasants. In addition, the large numbers of farmland water conservancy projects that have been constructed since the founding of the People's Republic have also played a major role in the fight against natural disasters.

In the 32 years since founding of the People's Republic, China has built more than 80,000 medium and small size reservoirs, more than 6 million small ponds, more than 2 million pump wells for agricultural use, and has developed more than 7 million horsepower of drainage and irrigation machinery. As a result, about 46 percent of cultivated land has irrigation facilities and 260 million mu of lowlying land has been brought under initial control. The building of these farmland water conservancy and farmland capital construction projects has provided a solid material foundation for increases in agricultural production. Last year drought in the six provinces of Hebei, Henan, Jiangsu, Anhui, Hubei, and Hunan covered a 150 million mu area; however, since these six provinces had substantial water conservancy facilities and put them to fair use, the disaster area was reduced to only 47 percent of the drought area, and total grain output increased by 18 billion jin over 1980. Meanwhile in Guizhou and Gansu provinces where water conservancy conditions are comparatively poor, the disaster area was more than 80 percent of the drought area resulting in a drop in output.

Of course, it is also necessary to realize, on the other hand, that benefits from existing farmland water conservancy facilities have not yet been realized to the full. In some places, because of consecutive years of drought with little rainfall, reservoir and pond water storage is in poor condition; the ground water table has dropped tremendously, and pump wells are unable to raise water. In other places the water storage situation is poor as a result of not having fully equipped facilities or poor management. Ways must be gradually found to conscientiously solve these problems.

Question 2: Following Institution of Agricultural Production responsiblity systems, what new problems did farmland water conservancy work encounter?

Answer: Since agricultural responsibility systems grew very quickly, in some places water conservancy was unable to catch up at once. In places practicing both the fixing of output quotas on a household basis and assigning full responsiblity for task completion on a household basis, in particular, some commune and brigade cadres threw up their hands and had nothing to do with farmland water conservancy work. As a result, in both project management and use of water for irrigation, some problems arose. Some projects fell into disrepair; little water was stored in reservoirs and ponds, water pumping equipment was poorly maintained or even stolen, sold, and privately divided, and the specialized water management corps was disbanded. In some places there were even instances in which [four characters illegible], ponds and reservoirs were abandoned and not used and destructive acts such as dynamiting and poisoning of fish perpetrated. Meanwhile water use and [one character illegible] use steadily increased. During periods of fight against drought there was competition for water and seizing control of water. In South China where there are ricefields that are irrigated and drained one after another, in particular, fights increased about "fields water traverses." The outbreak of the aforestated problems was due not to institution of agricultural production systems of responsibility but rather resulted from failure of our water conservancy work to keep up with the developing situation.

Question 3: In order to meet further the rural situation, where should the emphasis be placed now in farmland water conservancy work?

Answer: In view of the foregoing problems, farmland water conservancy systems of responsibility must be instituted to make full use of benefits from existing water conservancy projects.

With the approval and sending forward last year by the former State Agricultural Commission of the "Report on Nationwide Enhancement of Farmland Water Conservancy Work Responsibility Systems," almost 50 percent of farmland water conservancy projects throughout the country have instituted different forms of management responsibility systems. These include those in Shandong, Shanxi, Sizhuan, and Guizhou provinces where, because of serious attention on the part of leadership, the drawing of experiences gained at key points for promotion in all areas, and tailored guidance, progress has been relatively rapid. Facts have shown rather remarkable results from institution of farmland water conservancy responsibility systems as follows: First is fundamental solution to the problem of no one being in charge and impetus to water conservancy project repair and maintenance. Second is an intertwining of the responsibilities, rights, and benefits of management personnel, arousal of their enthusiasm not only for taking care of good use of project water but also for giving impetus to development of economic diversification for the realization of self-sufficiency in meeting project management expenses with some surplus. Third is increase in the in-operation rate of facilities, reduction in energy consumption, and a lowering of costs for lifting water. Fourth is institution of water conservancy building responsibility systems with the use of economic methods such as agreements systems, and contracting systems to institute plans and manage construction, increasing results obtained from use of water conservancy funds, hastening speed of project construction, and guaranteeing project quality.

Question 4: What is the form of farmland water conservancy responsibility systems currently in being?

Answer: In accordance with different circumstances, each jurisdiction has adapted general methods to local situations to adopt diverse forms of farmland water conservancy responsibility systems. In their form of management, mostly they are contract responsibility systems practicing the linking on the type of project, and differences in size and production team management systems, they have linked "responsibilities, rights, and priviliges" under the centralized leadership of communes and brigades and centering around "fixeds, contracts, and bonuses," with individualized practice of all around contracting, specialized contracting, contracting for individual tasks, and large scale assignment of responsibilities. In some places where irrigation districts cut across brigade lines, management of water use is done by centralized reporting to production teams on quantities of water used and times of use. Management units maintain an overall balance, send water to brigades, render payments above and collect fees from below, apportion water to teams and to households, and enforce payment of basic water fees and water fees based on calculation of quantities used, with increases in price for overuse. Water from small ponds is also under production team management for release with "the stroke of a hoe." Production teams centrally arrange the order in which people will receive water depending on their distance, and difficulties in providing water to them in a centralized allocation of water resources.

Those who have not yet established farmland water conservancy responsibility systems should take matters firmly in hand and build them with all possible speed. Those who have already established them should further perfect them.

Question 5: What new problems should be given attention in future farmland water conservancy construction?

Answer: As a result of 32 years of construction, China's farmland water conservancy endeavors have a definite foundation. For now and for a certain time in the future, the main task is strengthening of management to derive benefits. Emphasis should be placed on elimination of hazards and reinforcing projects, equipping them fully to tap potential, maintenance and replacement, as well as clearing away of sediment and preventing seepage, so that project benefits can be fully brought into play. In some places the foundation for water conservancy is weak, and if the problem of irrigating as yet unirrigated places in drought areas, and the problem of drinking water for people and livestock is to be solved, a certain about of new construction of medium and small projects will have to be done; however, action should be taken only within capabilities, with efficiency being the goal.

There are two situations in farmland water conservancy construction today that should arouse concern. One is that following practice of production responsibility systems, in order to improve production conditions, increase output and increase earnings, peasants have been very enthusiastic about the building of small farmland water conservancy projects. Communes and brigades have collectively invested funds, and groups of households have pooled funds in a spontaneous building of water conservancy projects, one after another. However, because organizational leadership and technical direction has not kept apace and because of a lack of necessary rules and regulations, projects have not been equitably distributed and quality of construction has been poor, which will mean a future waste of manpower, material and financial resources. Secondly, in some places commune and brigade cadres have thrown up their hands and have not cared, as a result, farmland water conservancy construction has stagnated. Not only have new projects that should have been built not increased, but because of lack of needed repairs, reinforcement, and replacement of equipment at existing water conservancy projects, it has been impossible to maintain even simple reproduction, resulting in needless losses for agricultural production. These two situations require close attention and solution.

In his government work report to the Fourth Session of the Fifth National People's Congress, Premier Zhao Ziyang noted that "It is necessary to make equitable use of the investment of labor of several hundred million peasants to carry out capital construction such as farmland water conservancy." Now, in the process of improving and consolidating agricultural production responsibility systems, many places have factored in workdays required for farmland water conservancy construction. Some areas have also made rules and regulations requiring workforces in every rural village to do a certain accumulated amount of required labor each year on farmland water conservancy capital construction. Politically, emphasis has been on continued adherence to the principles of those who benefit are to be responsible, and of voluntary participation and mutual benefit for exchanges at equal value and payment of compensation according to labor done, the greater the work the greater the gain. These methods are very good. I believe that with conscientious implementation of the programs and policies that have followed from the Third Plenary Session of the 11th Party Central Committee, steady elimination of the effects of leftist ideology, strengthening of leadership, reliance on the masses, and doing a solid job, farmland water conservancy construction will inevitably see further development, and will play a greater role in agricultural production.

EXTENSIVE FRESHWATER FISH BREEDING URGED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 1982 pp 20-21

[Article by commentator: "Strive by Every Available Means for Great Growth in the Fishing Industry"]

[Text] Since Liberation, China's aquatic product enterprises have seen definite development, and numerous typical instances of high yields have occurred. Nevertheless, in an overall sense, the fishing industry's output remains very low and there is always a shortage of fish supplies in markets. As a result of excessive and indiscriminate fishing, within a short period of time fishing industry resources have been seriously damaged, so that now catches must be controlled so that resources can rest and recuperate. Therefore, the trend of development in the fishing industry must inevitably be away from sole reliance on catches of natural resources to artificial freshwater and marine breeding. This is not only an effective way of increasing supplies of aquatic products now, but is also the long range, strategic method and direction for China's development of aquatic product enterprises.

Development of a freshwater breeding industry holds greater economic benefits than development of the livestock industry. The number of fish that can be raised in a cubic volume of water is much greater than the number of livestock that an equivalent amount of land will support. Fish are cold blooded animals whose energy consumption and feed requirements are less than for livestock or poultry, and the edible portions of which and the amount of protein provided from an equal quantity of feed is higher than from livestock animals or poultry. In addition, they help maintain the ecological environment, improve the structure of agriculture, and develop the rural economy in an all-around way so that the broad masses of peasants may prosper with all possible speed.

Ours is a vast land with widespread areas of water whose geographical position is temperate, favoring growth of fish. Traditional experience exists for the raising of freshwater fish, and the broad masses of people and scientists and technicians have created new techniques. China has bountiful resources and tremendous potential for development of a freshwater fishing industry. However, China has scant accumulated wealth, and its financial and material resources are limited. The work foundation for aquatic product departments themselves is also fairly poor. If the freshwater fishing industry is to be improved with all possible speed, the emphasis now should be toward doing the following five jobs.

1. Further Improvement of Understanding and Genuine Strengthening of Leadership. CCP committees and government at all levels, county level party and government leadership organizations in particular, must establish a greater agriculture concept with all-around implementation of a program of simultaneous development of farming, forestry, animal husbandry, sideline occupations, and fisheries, the same heavy emphasis given grain farming being devoted to the restructuring and use of water surfaces. The fishing industry has to be really placed on important daily agendas and forceful cadres made responsible for this work, attention being devoted to it several times each year for effective solution to genuine problems in production. While readjusting structures, all jurisdictions should establish and perfect the structure of the fishing industry, and assign a certain number of aquatic products cadres and technicians to it. Materials required by the freshwater fishing industry should be made a part of the plan for all-around arrangements to assure supplies.

2. Adherence To a Program For the Near Term of Development of the Freshwater Fishing Industry. Development of a freshwater fishing industry requires mobilization of forces in all areas and fullest use of all kinds of water surfaces in a combined program of breeding, multiplication, raising, and catching in which breeding is the key. Full use should be made of the leadership and exemplary role of state owned fishing industries. Emphasis should be on development of commune and brigade fishing industries, and commune member households and entreprenurial units should be encouraged to raise fish to produce a situation as rapidly as possible of joint efforts by the state, collectives, and individuals. Continued strong attention should be given the building of commodity fish bases to provide city and countryside with larger quantities of live, fresh fish. Cities themselves should develop suburban raising of fish in the same way that they took in hand production of fresh vegetables. Ponds, small lakes, and reservoirs have extensive water surfaces suitable for intensive raising of high yields. This will be the focus of development in the near term; however, one should not overlook use of the water surfaces that large lakes and large reservoirs provide. For large and medium size water surfaces, most important at the moment is diligent attention fo fully equipping the fishing industry, strengthening of management, multiplying resources, and sensible catches. Emphasis should be given the equitable use of water surfaces, general methods being adapted to specific bodies of water for development of diverse aquatic animals and plants.

3. Diligent Carrying Out of Various Fishing Industry Policies. Policies pertaining to water surfaces should be put into effect, and water surface use rights made clear and consolidated. The overall principle must be that whoever owns the water surface operates it. Also possible is the organization on the basis of voluntary participation and mutual benefit of various forms of joint ventures. No further changes should be made for water surfaces whose

use has been made definite. Water surfaces that straddle boundaries about which there are disputes should be resolved through consultations by all parties concerned in meetings convened by appropriate high leadership organizations. Lakes and streams belonging to the state that have not yet been put to use should, insofar as possible, be operated by communes and brigades. Odd fragments of water surfaces not readily amenable to collective operation may be designated for individual commune member operations. Once use rights have been decided on, no change is to be made for a long period of time and they are to be protected by the law.

Aquatic product procurement and marketing policies are to be put into effect. In order to enliven the economy and make markets boom, state fish farms, specialized communes and brigades and reservoir, and state farm and land reclamation unit fishing industry protection units must assure fulfillment of state assigned procurement quotas as regards both quality and quantity. Products in excess of assigned quotas may be disposed of by producing units as they see fit. The state has no assigned procurement quotas for fish raised by communes not specializing in the raising of fish or by commune member households, and such fish may be freely sold. In seting procurement and marketing policies, all jurisdictions must consider both what benefits fishing industry production, and assure urban residents a certain quantity of fish at parity price.

Putting into effect policies for fish feed supplies. Feeds needed by state fish farms, reservoirs, specialized fishing industry communes and brigades for the raising of fingerlings, and parent fish, and for raising of fish in net cages, and in warm running water, should be made a part of plan to be provided in accordance with pertinent State Council regulations, and quotas should be promptly readjusted in accordance with actual needs as production develops. Feeds needed for the raising of fish by rural communes and production brigades may be centrally withheld from feed grains or a certain amount of land may be designated for the raising of feed. Breeding of fish to meet state assigned quotas should be recompensed with supplies of feed grain, the level doing the procurement and dispatching the fish to the state receiving the grain.

Policies pertaining to protection of waterlands and aquatic product resources are to be put into effect. Protection of waterlands requires no enclosing of lakes, filling in of ponds or enclosing reservoirs to make farmland, and those that have been enclosed to reclaim land without compensation must be returned in a planned way to fishing. Industrial plants and mining enterprises are to be required to discharge waste water in accordance with environmental protection laws and fishing industry water quality standards. All who pollute fishing industry waters causing losses will have to pay compensation according to law, and the responsibility of leaders will be fixed. Funds required to build water conservancy projects and to construct necessary facilities to help succor fish should be made a part of plan for overall arrangements. When units concerned take over fishing industry grounds for capital construction or other needs, they must obtain permission and pay compensation in the same way as when requisitioning land. Resolute action must be taken to halt poaching, over fishing, poisoning of fish, and dynamiting of fish. All levels of party and government leadership organizations are to intensify ideological and political work so that fishing area cadres and the masses will have an enhanced conception of the law and will consciously struggle against the unhealthy trends and evil practices that cause damage to fishing industry production. Water police sub-stations are to be put back in operation on all large rivers, lakes, and reservoirs, and some state fishery farms may establish fishing industry police. Illegal conduct that seriously damages aquatic product resources and fishing industry production public procurator departments are to strictly handle according to the severity of offenses.

Fishing industry production responsibility system policies are to be carried out. Both state and collective fishing industry production units are to institute various forms of production responsibility systems in accordance with freshwater breeding characteristics, production conditions mass awareness, and levels of management. Where they have been established, so long as they benefit production and the masses are satisfied, they should be gradually perfected while being consolidated. Where they have not been established, a good job should be done to help gradual implementation.

4. Strict Attention To the Building of Key Projects. Development of a freshwater fishing industry requires that some capital construction be done. All jurisdictions may size up their own situation and devote attention to construction of key projects. A first requirement is continued serious attention to the building of commodity fish bases. Not only should the state, each province, municipality, and autonomous region with conditions operate them, but cities too should build their own commodity fish bases. State owned lake and reservoir fish breeding farms should emphasize full installation of equipment to increase production capacity. Collective fish raising pond and weir restructuring is to be included in farmland capital construction plans for each jurisdiction for overall arrangements. Mostly such restructuring will rely on commune and brigade resources for implementation. Second, attention should be given to building of fry and fingerling production. All jurisdictions should begin with strengthening of planning and management for fry and fingerling production at the county level using centralized planning and equitable distribution to maintain balanced planning for fry and fingerling production. Fine variety bases should be built to fully tap existing state owned fish farm and commune and brigade fish farm fry and fingerling production potential. Net cage breeding, ricefield breeding, and raising of adult fish and fingerlings in the same ponds should be encouraged.

5. Spread of Freshwater Fishing Industry Scientific and Technical Knowledge. For the freshwater fishing industry to advance, it has to take the road of scientific fish breeding. All jurisdictions are to do a good job of surveying and zoning fish resources, make the most of local advantages, and make rational selection of both water surfaces and varieties to be bred. The main targets for study should be problems requiring little effort to solve. Forces should be organized and the indigenous and foreign combined for a concerted attack to solve problems as quickly as possible so that China's traditional fish breeding techniques will be steadily improved, the better

to serve production. Counties and communes having a fairly large number of water surfaces should gradually build aquatic products technical promotion organizations, establish specialties and fishing industry technicians who are exempt or semi-exempt from production. They should also bring into play the role of "native experts." At the same time they should use various methods for popularizing freshwater fishing industry scientific and technical knowledge.

CCP Central Committee leadership comrades are extremely solicitous about development of the freshwater fishing industry and have set a target for struggle of trying to attain an output of 4 million to 5 million tons of freshwater fish by the end of the 1980's. Much arduous work will be required to realize this magnificent goal. All that is needed is serious attention by the party as a whole, arousal of the masses, reliance on policies and secondly on science, and solid efforts and great development of the country's freshwater fishing industry production is a certainty.

REGULATIONS GOVERNING QUARANTINE INSPECTION OF IMPORT, EXPORT ANIMALS, PLANTS

Beijing RENMIN RIBAO in Chinese 23 Jun 82 p 4

[Beijing XINHUA 22 June 82: "Recently the State Council has Issued "The People's Republic of China Regulations on Quarantine Inspection of Import and Export Animals and Plants," the entire text is as follows]

[Text] Section 1. General Provision

Article 1. These regulations are issued to tighten quarantine inspection of import and export animals and plants in order to protect the agricultural, forestry, animal husbandry, and fishery production of our country and the health of our people; to maintain our creditable reputation in foreign trade; to meet our international commitments; and to prevent the importation and exportation of diseases, pests, weeds, and other organisms harmful to animals and plants.

Article 2. The quarantine inspections provided in these regulations shall apply to all commercial and noncommercial animals, plants, animal and plant products, and the means of transporting same to enter, leave, or transit the People's Republic of China. The particulars are as follows:

(1) Animals: including domestic animals, domestic fowls, wild animals, bees, fish, silkworms, etc.

(2) Animal Products: including rawhides and pelts, furs, meats, internal organs, fats, blood, eggs, sperm, bones, hoofs, horns, etc.

(3) Plants: including cultivated plants, wild plants and their seeds, saplings, breeding materials, etc.

(4) Plant Products: including grains, beans, cotton, oil, hemp, tobacco, kernels, dry fruits, fresh fruits, vegetables, raw medicinal materials, logs, fodders, etc.

(5) Vehicles, vessels, and aircrafts used transporting animals, plants, animal and plant products as well as packaging, bedding and lining materials, and feeding utensils, etc.

Quarantine inspection shall also apply to other commodities and the means of transporting them which could carry quarantine objects.

Article 3. Infectious animal diseases and parasites, harmful plant diseases and pests, weeds, and other harmful organisms (generally known as diseases and pests) are classified as quarantine objects, and diseases and pests subject to inspection.

(1) Quarantine objects are diseases and pests barred from entering the country. A list of quarantine objects shall be published by the Ministry of Agriculture, Animal Husbandry and Fishery.

(2) Diseases and pests subject to inspection are those diseases and pests required to be inspected by agreements, accords, or commercial contracts with foreign countries, or upon application by any export unit for quarantine inspection.

Article 4. Animal and plant quarantine inspection offices or stations (generally known as port animal and plant quarantine inspection authority) established by the People's Republic of China at its ports, airports, land and river border ports open to international traffic, and in related provincial capitals and the capitals of the autonomous regions shall represent the state to perform quarantine inspection on import and export animals and plants.

Article 5. All import and export animals, plants, animal and plant products, and their means of transport must have quarantine inspection clearance before they shall be permitted to enter or leave the country.

Section 2. Import Quarantine Inspection

Article 6. Prior approval of the Ministry of Agriculture, Animal Husbandry and Fishery shall be required for the importation of animals and animal products. Prior approval of the Ministry of Forestry shall be required for the importation of wild animals and their products.

To import seeds, saplings or breeding materials, the importing department, if it is an agency of the State Council, shall file a "Quarantine Inspection Form for Import Seeds and Saplings" with the Ministry of Agriculture, Animal Husbandry and Fisher or the Ministry of Forestry for approval; or if the importing department is an agency in an appropriate province, autonomous region and municipality it shall file for approval in the deparment (bureau) of agriculture (forestry, reclamation) of that province, autonomous region and municipality.

Article 7. Commercial contracts or agreements of technical cooperation, gift, exchange or aid which cover the importation of animals, plants or animal and plant products shall specify the quarantine inspection requirement of the state, or the quarantine inspection agreement reached between the governments concerned, and the requirement of quarantine inspection certificates issued by the appropriate authorities of the exporting countries.

Article 8. Import animals, plants, and animal and plant products shall be subject to quarantine inspection by the port animal and plant quarantine inspection authority.

(1) Before or upon the arrival of the commodity at the port of entry, the consignee unit or its agent shall file an application for quarantine inspection (or bill of lading) and the quarantine inspection certificate issued by the exporting country with the port animal and plant quarantine inspection authority to ask for inspection.

(2) The quarantine inspection of an incoming train or automobile shall be performed on board the vehicle by the port animal and plant quarantine inspection authority in conjunction with the joint inspection, or on board an incoming vessel after the joint inspection, or on the spot where cargo is unloaded from an incoming aircraft.

Article 9. If neither quarantine objects nor diseases and pests subject to inspection are detected during the inspection, the imported animals, plants, or animal and plant products in question shall be permitted to enter the country after receiving a "quarantine clearance notice" or a "quarantine clearance chop" stamped on the bill of lading.

Article 10. If import animals or animal products are found to contain quarantine objects or diseases and pests subject to inspection, the applicant for inspection shall be issued, appropriate to the situation, a "quarantine treatment notice" to inform him of the different measures to be taken:

(1) The animal with a serious infectious disease and the whole shipment thereof shall be returned, or slaughtered and destroyed.

(2) The animals with a common infectious disease shall be returned or slaughtered and destroyed; and the whole shipment thereof shall be kept at an animal quarantine center or any designated insulation area for observation.

(3) The animal with an infectious disease shall be given medical treatment.

(4) The contaminated animal product shall be sterilized, returned, or destroyed.

Once the animals quarantined for observation in accordance with (2) and those given medical treatment in accordance with (3) are found free of diseases, and once the animal products sterilized in accordance with (4) are cleared of contamination, they shall be permitted to enter the country.

Article 11. If import plants or plant products are found upon quarantine inspection to contain quarantine objects or diseases and pests, the applicant for inspection shall be issued a "quarantine treatment notice" to inform him to fumigate, sterilize, restrict the use of, return or destroy the imports in question. After decontamination by fumigation and sterilization, the imports shall be permitted to enter the country once they are cleared by inspection.

Article 12. The quarantine inspection and treatment of import animals, plants, or animal and plant products shall be performed at the port of entry.

If, due to lack of facilities at the port of entry or for any other reason, the treatment should be performed at a designated locality inland, the approval of the Ministry of Agriculture, Animal Husbandry and Fishery shall be required. To prevent possible spread of the infections, the shipment, loading and unloading thereof shall be strictly monitored, and the local quarantine inspection authorities shall be asked to supervise the operations.

Article 13. The sites, warehouses, means of transportation, bedding and lining materials, and feeding utensils contaminated by the quarantine objects or diseases and pests subject to inspection shall be treated by the applicant for inspection or the consignee in accordance with the requests specified by the port quarantine inspection authority.

Article 14. The port animal and plant quarantine inspection authority may, in accordance with the conditions, issue quarantine inspection certificates to imported animals, plants, and animal and plant products which are found upon quarantine inspection to contain quarantine objects or diseases and pests subject to inspection.

Article 15. The importation of the following items shall be barred:

(1) Pests harmful to health, animal and plant pathogenic microorganisms (including starters, toxins and bioproducts), and other harmful organisms.

(2) Animals, seeds, saplings, breeding materials, and easily infected animal and plant products from any country or region affected by serious epidemics.

(3) Soil.

The Ministry of Agriculture, Animal Husbandry and Fishery shall issue a list of the items barred from importation by the aforesaid provisions. In case the importation of any items thereof is required for scientific research, the importing unit shall file an application with the Ministry of Agriculture, Animal Husbandry and Fishery for special permission to import them.

Section 3. Export Quarantine Inspection

Article 16. To export animals, plants, plant products, and noncommercial animal products for which quarantine inspection is required, the exporting unit or its agent shall file an application for inspection and the quarantine inspection certificates issued by their place of origin with the port animal and plant quarantine inspection authority for inspection. Those cleared upon inspection shall be issued quarantine inspection certificates and released. The export quarantine inspection of commercial animal products shall be performed by the import and export commodity inspection authority.

Article 17. Export animals, plants, and animal and plant products which are found upon quarantine inspection to contain diseases and pests subject to inspection shall be barred from export, or permitted to export after decontamination treatment.

Article 18. The contamination sites, warehouses, means of transport, bedding and lining materials, and feeding utensils shall be treated in accordance with the provisions of Article 13 of these regulations.

Section 4. Quarantine Inspection of Passenger-carried Items

Article 19. The quarantine inspection of animals, plants, and animal and plant products carried or shipped by incoming passengers or by transport staff and workers shall be performed at the port of entry. If no quarantine objects are detected upon inspection, they shall be cleared and released. If quarantine objects are detected, they shall be barred from entry, or cleared and released after sterilization. If results of quarantine inspection are not readily available on the spot, they shall be impounded for inspection, and the owner shall be notified of the findings and treatment.

Article 20. Raw meats carried out shipped by incoming passengers or by transport staff and workers shall be given antiepidemic treatment before clearance for entry.

Article 21. Animals, plants, and animal and plant products carried or shipped by outgoing passengers or by transport staff and workers shall be given necessary quarantine inspection and issued quarantine inspection certificates.

Section 5. Quarantine Inspection of International Postal Parcels

Article 22. Plants and plant products entering the country by mail shall be inspected by the port animal and plant quarantine inspection authority, and a postal quarantine clearance chop shall be stamped on the inspected postal parcel and released. If quarantine objects are detected, the postal parcel, after receiving quarantine treatment, shall be issued a "quarantine treatment notice" and turned over to the post office for delivery to the addressee. In case quarantine treatment cannot be performed, the postal parcel shall be labelled rejected and turned over to the post office for return to the sender. If the postal parcel should be destroyed, a "quarantine treatment notice" shall be issued for the post office to forward to the sender.

Raw animal products shall not be permitted to enter the country by mail (except small amounts of samples).

Article 23. Plants, and animal and plant products leaving the country by postal parcels shall be given necessary quarantine inspection and issued certificates.

Article 24. Pests harmful to health, animal and plant pathogenic microorganisms (including starters, toxins and bioproducts), other harmful organisms, and the natural enemies of diseases and pests sent into the country by mail shall be covered by permits issued by the Ministry of Agriculture, Animal Husbandry and Fishery.

Section 6. Transit Quarantine Inspection

Article 25. The shipping attendant or carrier of animals, plants, and animal and plant products in transit shall file an inspection application form (or bill of lading), and the quarantine inspection certificates issued by the exporting country with the animal and plant quarantine inspection authority at the port of entry for quarantine inspection. No further quarantine inspection shall be required at the port of departure.

Article 26. If plants, animal and plant products shipped in transit by train, automobile, or aircraft change train, automobile or aircraft in a port within our territory, the exterior of the packages shall be inspected during the change. If they transit in the original vehicle or aircraft, the exterior of the vehicle or aircraft shall be inspected. If no quarantine objects are detected upon inspection, a "quarantine clearance notice" shall be issued or a quarantine inspection release chop shall be stamped on the bill of lading to allow the shipment to pass through. If quarantine objects are detected, the whole shipment shall be turned back. The contaminated sites and tools used shall be treated in accordance with the provisions of Article 13 of these regulations.

Article 27. Animals shipped in transit shall be permitted to pass through if they are found upon quarantine inspection to be free of quarantine objects. The whole shipment shall be turned back if they are affected with quarantine objects. The sites and tools thus contaminated shall be treated in accordance with the provisions of Article 13 of these regulations. During transit, animal fodder, excrement, bedding straw, dirt, and carcasses shall be disposed of at designated localities, not to be abandoned at will.

If quarantine objects are detected in the fodder for the animals in transit, the shipping attendant shall be notified to change it and sterilize the contaminated fodder on the spot.

Section 7. Penalities

Article 28. Commensurable penalties, including criticial instructions, disciplinary action or fines shall be given when provisions of these regulations are violated. Serious violations shall be dealt with by the judicial authorities in accordance with the law.

Section 8. Supplementary Provisions

Article 29. When a port animal and plant quarantine inspection authority performs its duties at a port, airport, railroad station, post office, or warehouse, the particular units concerned shall render all necessary assistance.

When quarantine inspection is performed on the spot, the applicant concerned shall be present to handle the moving, unpacking and repacking work.

A port animal and plant quarantine inspection authority shall issue receipts for any samples it selects for tests.

Article 30. When a department concludes with a foreign country any agreement, accord, or commercial contract which provides for quarantine inspections, it shall immediately notify the port animal and plant quarantine inspections, it shall immediately notify the port animal and plant quarantine inspection authority concerned.

Article 31. All port animal and plant quarantine inspection personnel shall wear quarantine uniforms and badges while performing quarantine inspections.

Article 32. A port animal and plant quarantine inspection authority may charge fees for performing quarantine inspections, and the specific measures therefor shall be prescribed by the Ministry of Agriculture, Animal Husbandry and Fishery.

Article 33. The rules for carrying out these regulations shall be laid down jointly by the Ministry of Agriculture, Animal Husbandry and Fishery and the Ministry of Forestry.

Article 34. These regulations shall take effect on the day of promulgation.

NEW PESTICIDE DEVELOPED TO CONTROL APHIDS

Beijing RENMIN RIBAO in Chinese 11 May 82 p 1

[Article by the Office of Biological Prevention and Control of the Chinese Academy of Agricultural Sciences: "A New Agricultural Chemical for Biological Prevention and Control--Aphidicide"]

[Text] Aphidicide is the first new antibiotic pesticide for agricultural use developed and manufactured by our country on its own. Over the past 4 years, tests and demonstrations conducted on over 50,000 mu in 14 provinces, municipalities, and autonomous regions throughout the country have shown that aphidicide is effective in preventing and controlling orange rust tick, bloated red spider, apple red spider, cotton, aphid, and radish aphid. This new agricultural chemical has two main characteristics: it only kills the harmful insects and does not harm their natural enemies--the ladybug and the grass sandfly; its application density is low (6-15 parts per million), its residual period is short (72 hours), and it is not harmful to people or animals.

There are marked benefits from using aphidicide on economic crops. If used on oranges, its cost per mu is 15 to 30 percent lower than that of commonly used chemical pesticides, the ratio of insects to fruit is lowered by 15 percent, and the per mu income is increased by 42 yuan.

This biological achievement was tested and researched by the Microbiology Institute of the Zhejiang Provincial Academy of Agricultural Sciences. It was approved by the 1982 national aphidicide appraisal conference. This year it will be popularized and applied in eight provinces (autonomous regions), viz, Guangdong, Jiangxi, Ningxia, Anhui, Jiangsu, Shandong, Liaoning, and Zhejiang. In order to further meet the demand for its popularization and application, the Petrochemical Industry Bureau of Zhejiang Province has brought this new agricultural chemical into line with the 1982 state production plan by making the Tonglu and Tongxiang agricultural chemical plants responsible for its production.

NATIONWIDE CONTROL OF COTTON FUSARIUM, VERTICILLIUM WILT PLANNED

Beijing ZHONGGUO NONGMIN BAO in Chinese 3 Jun 82 p 1

[Article: "Control of Fusarium Wilt and Verticillium Wilt of Cotton With All Possible Speed Is Requirements of National Cotton Quarantine Techniques Conference"]

[Text] In order to control with all possible speed the spread of fusarium wilt and verticillium wilt in the nation's cotton, the Agriculture, Animal Husbandry and Fishing Industry Ministry recently convened at Taian in Shandong Province a "National Conference on Cotton Fusarium and Verticillium Wilt Quarantine Techniques," which set June to September this year as the time for a national survey of fusarium and verticillium wilt in cotton.

Cotton fusarium and verticillium wilt first appeared in the United States, and was brought into China with the introduction from the United States of Stoneville cotton in the 1930's. They are two destructive diseases for cotton production. Once cotton contracts these two diseases, yields drop by a general 20 to 30 percent, by more than 60 percent in serious cases, or abort entirely. China's cotton production has developed fairly rapidly in recent years, the area planted steadily increasing. However, because some cotton growing areas viewed as important only increased cotton output to the neglect of fusarium and verticillium wilt quarantine prevention and control work, the area of incidence of these two diseases has steadily spread. The area stricken with these two diseases amounts to 20 percent of the total, and annually about 2 million dan of ginned cotton are lost. This February the State Council issued a notice requiring all cotton growing areas to take immediate action to bring these two diseases under control within 2 to 3 years in order to assure healthy development of China's cotton production. The present conference exchanged experiences about implementation of the spirit of the State Council notice in the prevention and control of cotton fusarium and verticillium wilt. It heard the views of experts, listened to specialized reports, and discussed formulation this year of specific methods and technical standards for a national survey of cotton fusarium and verticillium wilt. The conference asked that departments concerned in all cotton growing areas strengthen leadership and cooperate with local plant quarantine departments in carrying out this survey, and take effective action to control the continued spread of cotton fusarium and verticillium wilt. Delegates from 381 key cotton producing counties in 18 of the nation's provinces, municipalities, and autonomous regions attended this conference.

BRIEFS

SUMMER GRAIN PROCUREMENT--By 28 June, Taihe County, Anhui Province had put 62.06 million jin of summer grain into the state granary, overfulfilling the original grain procurement quota. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 2 Jul 82 OW]

SHUCHENG COUNTY RICE DISEASE--Anhui's Shucheng County has drawn up a plan for protecting its early crop from a disease called sheath and culm blight of rice. The plan calls for spraying 120,000 mu of affected early rice with insecticide. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 3 Jul 82 OW]

XIAOXIAN COUNTY COTTON DISEASE--Commune members in Xiaoxian County, Anhui, are actively engaged in combating cotton bollworms. By 22 June, prevention work had been carried out on the county's 240,000 mu of cotton. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 3 Jul 82 OW]

DANGTU COUNTY COTTON PRODUCTION--Cadres and commune members in Anhui's Dangtu County are stepping up cotton field management in order to ensure a bumper harvest this year. As a result, the county's 114,000 mu of cotton are growing well. [OW271137 Hefei Anhui Provincial Service in Mandarin 1100 GMT 3 Jul 82 OW]

EDITORIAL RALLIES NORTH CHINA TO RENEWED FARMING EFFORTS

Beijing ZHONGGUO NONGMIN BAO in Chinese 30 May 82 p 1

[Editorial: "Rouse Enthusiasm, Do Overall Planning and Wage the Battle of Planting, Harvesting, and Providing Field Care"]

[Text] This year spring drought is severe in North China; however, because all jurisdictions have made great efforts to combat drought to assure a wheat harvest and to assure spring planting, in most areas of the country the summer grain situation will be better than had been formerly predicted. Spring planting quotas have been virtually completed according to plan, and quality of sowing has been generally pretty good. Now "grain fills" [around 21 May] has passed and in the basin of the Chang Jiang and the Huai, as well as in the middle and lower reaches of the Huang He, the busy season of the "three summer jobs" [planting, harvesting, and providing field care] is advancing. This requires the harvesting of several hundred million mu of wheat as well as the planting of several hundred million mu of summer crops, plus caring for several hundred million mu of spring sown grain, cotton, and oil-bearing crops. Effectiveness in the "three summer jobs" production is a crucial battle for winning a bumper harvest in agriculture for the year as a whole.

This year the "three summer jobs" production differs from former years. First of all, in wheat production there has been more practice this year than last of responsibility systems linking remuneration to output, and harvesting and threshing is fairly dispersed. Second, combatting drought to do summer planting is a big job. The drought affected area of North China now stands at close to 200 million mu, and some of the land that cannot be planted in spring will have to be switched at once to summer planting. Third, the cottonfield area has increased in Hebei, Shandong, and Henan provinces, and wheat harvest time is also a crucial time for cottonfield care, so conflicting demands on labor for summer harvesting and summer field care will be even more pronounced. Fourth is insufficient energy with a shortage of petroleum and electricity. The aforestated new situation has intensified difficulties with production quotas for the "three summer jobs," and this requires that leaders at all levels rouse enthusiasm, do overall planning, and make the most of advantageous conditions to overcome disadvantageous factors in an effort to wage this "three summer jobs" war well.

Because of the increased amount of hot dry weather during the last 10 days of May, wheat harvest time is expected to come earlier, and the wheat harvest is a priority task. All jurisdictions must make ready their threshing floors and further implement and perfect farm machine management responsibility systems to make the most of the role of farm machines. They are to adapt general methods to specific situations, give tailored guidance, do an effective job of organizing for the wheat harvest, organize cadres, technicians, and old peasants to make a field by field appraisal of the wheat and to set up a time sequence for harvesting, each field being harvested when it is ripe, every grain being harvested and every grain being threshed. In the case of brigades practicing both the fixing of output quotas on a household basis and assumption of full responsibility for task completion, production teams should strengthen leadership and conscientiously organize cooperation among households, the exchange of labor, and making arrangements for threshing grounds and threshing to assure that the myriad households can harvest and thresh wheat promptly. They should assiduously work to prevent molding and rotting in rainy overcast weather, and to prevent fire. They should act to insure priority for the harvesting of fine wheat and strictly prohibit robbers from cheating the collective out of its wheat. Effective work should be done in the selection and holding back of seeds, holding back enough seeds for fall planting. Seed units should actively organize purchase and supply work.

In spring it is the days that count, and in summer it is the hours. While working on the wheat harvest, the opportune time for summer sowing cannot be lost. Effort must be put into early sowing and sowing well. Sufficient grain crops and economic crops have to be grown in accordance with state plan. The grain sowing area must be maintained stable with no reductions. Intercropping of corn in wheatfields is an effective method in North China for making full use of climatic and soil resources, for accentuating strengths and downplaying weaknesses, for moderating the conflict over labor, and for increasing output and earnings. General methods have to be adopted to specific situations, and every effort made to expand the intercropped area. In the basins of the Huang He and the Huai He, summer sowing of soybeans offers numerous advantages, and the growing of some soybeans over a certain area may be suitably revived. In seriously drought stricken areas of North China, some planting of summer sweet potatoes can be done. In drought stricken areas, combat against drought should continue in order to assure summer sowing, with efforts made to plant early, a day being a day and another mu planted being another mu.

Though most areas have done their spring planting pretty much on time this year, and though quality is also good; still, during the seedling growth stage the drought in some places has resulted in missed seedlings and black spots in furrows. Suitable arrangements should be made about workforces and time for serious attention to inspecting the seedlings, adding seedlings, thinning seedlings, singling seedlings, and combating drought to protect the seedlings for a good job of field care of the spring sown crops. Weak seedlings and third grade seedlings should be promptly cultivated, watered and fertilized so that they will move up in grade. Good prevention and control of diseases and insect pests should be done, and preparations should be made organizationally and materially to combat drought and guard against waterlogging.

The "three summer jobs" are big ones and time is short. Leaders at all levels are to go down into the frontlines of production to unearth problems and promptly solve them. All trades and industries should energetically support the "three summer jobs," and do a good job of transporting and supplying farm implements, petroleum fuel, electricity, chemical fertilizers, and agricultural pesticides. They should also do a good job of preparing for summer distributions, adhere to the seeking of truth in facts, diligently verify summer outputs, and show concurrent concern for the welfare of the state, the collective and individuals, and do a good job of summer grain and oil-bearing crop state procurement work.

INSTRUCTIONS GIVEN ON HANDLING OF SUMMER GRAIN PROCUREMENT

Beijing ZHONGGUO CAIMAO BAO in Chinese 29 May 82 p 1

[Article: "Take Firmly in Hand Fulfillment of Summer Grain State Procurement Quotas"]

[Text] Summer grain crops will soon be arriving steadily at threshing grounds. This year is the first year for practice of assigned responsibility for state grain procurement, marketing, allocations and transfers with no change guaranteed for 3 years. Taking firmly in hand fulfillment and overfulfillment of summer grain state procurement quotas has a major bearing on winning the initiative in grain work for the year as a whole, for next year and the year after, for providing well for urban and country people's livelihoods, and for assuring national construction needs.

In some of the major wheat growing regions of North China a protracted drought has taken place since last year's fall sowing, and in some of the summer grain growing regions of South China low temperatures and much rain was encountered during the early stage. However, thanks to the strengthening of leadership at all levels of CCP committees and government, the further perfection and improvement of agricultural production responsibility systems, organization of the broad masses of peasants to fight drought and drain away waterlogging, and intensification of field care, damage caused by natural disasters was greatly reduced. This is the overall situation for the country as a whole. However, looked at in local terms, an uneven picture of fatness and leanness appears. Bumper harvest provinces and regions have places and communes and brigades with lean harvests. Lean harvest provinces and regions have places and communes and brigades with bumper harvests too. For this reason, in this year's summer grain procurement, it will be necessary to follow a program of the fat augmenting the lean. It will be necessary to strengthen ideological and political work, and to indoctrinate the broad masses of peasants in the "three concurrent concerns" to induce them to correctly handle relationships among the state, collectives and individuals, to surrender more grain and better grain to help disaster areas, and to support the national building of socialism as a glorious duty. All major producing provinces in North China must sell more wheat from bumper harvest areas. South China rice and wheat producing areas are also to actively fulfill and overfulfill summer great state procurement quotas so long as they do not impair state procurement of husked rice.

Last year some areas instituted quarterly price increases for grain and quarterly settlement of accounts. Production teams and commune members thus obtained increased prices for summer grain. This helped augment production funds and also helped the state procure more summer grain. Nevertheless, some problems exist in work, principally that some production teams and commune members sold summer grain in excess of quotas obtaining a higher price, but did not fulfill basic procurement figures in the fall, and the state could not retrieve the higher price it had paid for excess procurement. This year it is necessary to summarize experiences and to follow the principle of concurrent concern for the welfare of the state, the collective and individuals, further perfecting methods for paying increased prices for excess procurement of summer grain. In addition, there will have to be strict accounts settlement procedures to guard against mistakes and to plug loopholes.

In order to assure smooth fulfillment of summer grain state procurement quotas, during the procurement season each jurisdiction should intensify market management. All who have not fulfilled their summer grain procurement quotas may not send summer grain to market, nor should grain departments make purchases from them at negotiated prices. After state procurement quotas have been fulfilled production teams and commune members having surplus grain should be mobilized to continue to sell the excess to the state so that the fat will augment the lean. In addition, in accordance with the principle of marketing at the prevailing market price, slightly lower than the market price, negotiated purchases should be actively begun. It should be reiterated that grain and oil commodities must be regulated by the centrally administered policies of grain departments, and other departments and units are not permitted to intervene. Unless they receive permission, they may not go to rural production teams and markets to buy up grain and oil.

The summer grain procurement season is short, strongly seasonal in nature, and much work has to be done. All levels of CCP committees and government must strengthen leadership and give firm attention to the job of procuring and storing grain. They must sensibly organize the transportation of grain and promptly move away local surplus grain, emptying out the storage space so that it can accept new grain. They must set up a network of procurement points in a rational way, train personnel, and do a good job in preparing materials and regulating funds, organize mass sales in a planned way, and prevent problems arising of "difficulties in selling grain." They are to adhere to quality standards, arrive at prices on the basis of quality and neither inflate quality to raise prices nor depreciate quality to depress prices. While doing a good job of grain procurement and storage, they should also give attention to providing for the livelihood of the masses in areas hard hit by disasters.

INCREASED SOYBEAN PRODUCTION HIGHLIGHTED

Summer Soybean Production

Beijing ZHONGGUO NONGMIN BAO in Chinese 24 Jun 82 p 2

[Text] Every part of a soybean is precious. The root nodules and the leaves replenish the soil's organic material and improve the soil's granular structure; the soybean stalks and soybean cake make fine livestock feed; and the protein content of soybeans is 40 percent, higher than that of any grain crop. The protein content of 1 jin of soybeans is equivalent to that of 4 jin of corn or 5 jin of rice. Development of soybean output bears on the national economy and the people's livelihood, and on growth of agriculture and livestock industry; consequently, it is receiving increasingly serious attention in all countries of the world.

China is the home of the soybean and has several thousand years experience in farming it. In 1953, China held first position in both quantity of soybean output and quantity of soybean exports. However, after 1958, for various reasons tremendous curtailment occurred in the soybean growing area, and total output steadily declined. Despite some revival during the past 2 years, the comeback has been slow bringing about a conspicuous contradiction between supply and demand for soybeans, which hurts improvement in the people's livelihood. Consequently, major efforts to bring about a rise in soybean output is an urgent task confronting us.

The basins of the Huang, Huai, and Hai rivers are one of the major areas of soybean concentration in the country, accounting for about 45 percent of both the growing area and the output of soybeans in the country. This region has very great potential for both increases in the growing area and for improvements in yields per unit of area. Therefore, revival and development of soybean production in the Huang-Huai-Hai basin will mean a great change in the soybean production situation for the country as a whole.

Revival and development of soybean production will require, first of all, solution to two problems. One is the need for a correct understanding, i.e. the way of looking at soybean "low yields." Owing to differences in the physiological conditions for various crops, great differences in size of yields exist. It is indeed true that the yields obtainable from soybeans are somewhat lower than from grain crops; however, their protein content is several times that of corn, wheat, or rice. Therefore, when looking at the size of yields, we should look at both the quantity and quality. At a recent symposium of soybean production in the Huang-Huai-Hai basin, numerous counties having yields of more than 200 jin per mu, communes and brigades having yields of more than 300 jin per mu, and high yield examples of more than 400 jin were reported. These show that when leaders give serious attention and devote to soybeans the same energy they devote to wheat, rice, corn, and cotton, actively promote effective measures for increasing yields, and give painstaking attention from planting till harvesting, new breakthroughs can be scored in soybean yields. Second is the need to implement policies to assure that current soybean porcurement prices remain stable without change. It is also necessary to conscientiously solve problems relating to procurement, transportation, and foreign trade to arouse further peasant enthusiasm for growing soybeans.

Growth of soybean production requires that a certain growing area be guaranteed. Crop patterns require practice of an equitable crop rotation system that both devotes attention to grain production and requires adaptation of general methods to local situations for appropriate expansion of the soybean growing area. The Huang-Huai-Hai river basin grows two crops of soybeans a year, and fields from which wheat has been harvested should be resown to soybeans in summer. Some places can also vigorously promote the intercropping of corn and soybeans during the summer, or use ridges between fields for the growing of soybeans. Yields per unit of area must be increased, efforts put into increasing total output, solution found to the problem of sloppy management of soybean farming, experiences with high yields summarized, and research results promoted for further improvement in scientific farming of soybeans.

Summer Soybean Yields

Beijing ZHONGGUO NONGMIN BAO in Chinese 24 Jun 82 p 2

[Text] In view of the natural climate characteristics and experiences with bumper harvests in areas sown to soybeans during the summer, winning a bumper summer soybean harvest requires taking the following effective technical measures to increase yields.

1. Early Sowing For a Full Stand

The summer soybean growing season is short and is frequently restricted both by the time of harvesting of the previous crop and the time of sowing of the subsequent crop. Consequently, "no interval exists between the harvesting of wheat and the planting of soybeans." Soybeans have to be planted even while the wheat is being harvested in an effort to sow early so as not to miss the farming season.

In order to get a full stand from early sowing, the wheat stubble from the previous crop should be plowed under and sown so as to be able to work the soil to conserve soil moisture and get a full stand of seedlings. Dibbling of seeds may also be promoted as a means of taking advantage of available soil moisture for early planting, to assure quality of sowing, to attain a full stand of evenly spaced seedlings, and so that fields can be readily cared for. Dibbling can increase yields by 10 percent over drilling of seeds in rows.

2. Reasonably Close Planting and Promotion of Hand Thinning of Seedlings

Today problems exist in overly close sowing of soybeans or serious gaps in seedlings. Through the promotion of hand thinning, plants that have been too thickly sown may be used to fill in sparsely planted places to get the right density and to get rid of weeds to help soybean seedling growth. Thinning of seedlings has to be done early and lightly. Generally the time to begin is when the cotyledon appears and the hand is able to take hold of the seedling. Each mu should contain a stand of between 15,000 and 20,000 seedlings.

3. Reasonable Fertilization

Because the time for rush harvesting of wheat and rush planting of soybeans is short, and time is required to prepare the land, fertilizing cannot be done, so during the flowering stage of seedlings, quick acting nitrogenous and phosophate fertilizer applications help branching, differentiation of blossom buds, and fruiting of blossoms. Generally between 10 and 20 jin per mu of standard nitrogenous fertilizer should be applied. After the soybean growing season is over, the root nodules gradually deteriorate and absorption of fertilizer by the root system declines, so prompt top dressings of fertilizer should be given. The way to do this is as follows: 1 shijin of urea, 3 jin of calcium supersphosphate in solution, and 0.7 jin of potassium sulfate per mu, or else 0.7 jin per mu of potassium dihydrogen phosphate. Water should be added to make 150 jin and the leaves sprayed toward evening on an overcast day, spraying done once every 7 days for a total of three time for a 10 to 15 percent yield increase.

4. Prompt Cultivating and Hoeing of weeds

When soybeans are sown as a crop following wheat, it is the end of the dry season and the beginning of the wet. When seedlings reach a full stand, in conjunction with the final thinning of seedlings, the first cultivating should be done. The second cultivating should be done at the end of June or the beginning of July, and the third cultivating done before the rows grow shut, prompt weeding being done at the same time.

5. Prevention and Control of Diseases and Insect Pests

In the Huang-Huai-Hai soybean growing area, the major diseases, insect pests and weeds are grubs, soybean moths, zaoqiaochong [6644 2890 5722], beanstalk flies, beanpod borers, bean eating insects, virus diseases, downy mildew, and soybean Chinese dodder.

Control methods. Before the rows of beans grow shut, a combination of hoeing and spreading of soil treated with pesticide (1.5 jin of a six percent benzene hexachloride powder added to 70 or 80 jin of soil) should prevent grubs. During the young larva stage of bean moth and diqiaochong, spraying may be done with either dipterex or dichlorvos. For beanstalk flies, spraying of adults with a pesticide should be done. For control of bean eating insects and beanpod borers, poison bait (20 - 40 jin of wheat bran containing 2 - 3 liang of dichlorvos per mu), should be set out on sticks stuck into the ground. When Chinese dodder is found, it should be thoroughly removed, taken out of the field and destroyed.

Steady Soybean Output

Beijing ZHONGGUO NONGMIN BAO in Chinese 24 Jun 82 p 2

[Text] Revival of soybean production in Henan Province has been very rapid during the last 3 years. In the 3 year period from 1979 to 1981, the average annual increase in area sown has been 2,508,000 mu for a gross output increase of 745 million jin. In 1981, soybean yields per unit of area, total output, and commodity rate all set record highs.

Henan Province is one of the major summer soybean growing areas in the country. Following Liberation, soybean output rapidly developed. After 1958, however, as a result of interference from erroneous "leftist" ideology and a one sided emphasis on high yield crops with grain being favored over beans, plus the inequitable price paid for soybeans, both the area planted to soybeans and output gradually declined. Since the Third Plenary Session of the 11th Party Central Committee, Henan Province has made the most of advantages for growing soybeans, has equitably readjusted crop patterns, and has reinstated the soybean growing area. Soybean production has been revived in Henan largely on the Huang-Huai Plain and in eastern and south central Henan, intermediate and low yield areas where soil fertility is not high. In some intermediate and high yield areas, intercropping of soybeans and corn has been done so that, while assuring a certain total output of grain, the soybean growing area is year by year being reinstated to the 17.9 million mu of 1981. In addition, a responsibility system linking output to calculation of remuneration has been generally instituted for soybean production; technical guidance has been improved; technical training has been launched; and scientific and technical households have been established. The broad masses of peasants have actively added to the numbers of draft animals, done more work, fertilized more, used fine varieties and have planted well and cared for crops painstakingly so that bean output has steadily mounted and many representative examples of high yields have appeared. In 10 communes in Tanghe County, yields have been more than 250 jin per mu. In Xiangcheng County, 700 households had produced yields of more than 400 jin per mu from 2,800 mu of soybeans. In order to make soybean production rise, Henan Province has decided over the next several years to "stabilize the growing area, launch the main attack of higher yields per unit of area, increase total output, and increase the commodity rate."

PRE-HARVEST INSTRUCTIONS GIVEN ON WINTER WHEAT CARE

Beijing ZHONGGUO NONGMIN BAO in Chinese 6 May 82 p 1

[Article: "What Has To Be Done About Late Season Wheatfield Care? Officer in Charge of Agriculture, Animal Husbandry and Fishing Industry Department Answers Reporter's Questions"]

[Text] What is the current situation in winter wheat production? What work has to be done in caring for late season wheatfields in order to obtain a bumper harvest? The newspaper's correspondent visited the Agriculture, Animal Husbandry and Fishery Department to ask these questions, and the officer in charge replied as follows.

After the wheat was planted last fall, because of the drought in the north and waterlogging in the south, low temperatures, and small cumulative temperatures during the winter season, the wheat seedling situation at the onset of winter was everywhere not as good as during the previous year. However, as a result of the further institution of production responsibility systems, last winter and this spring firm attention was given to wheatfield care. Between mid-December and early March, temperatures were higher than in most years; cumulative temperatures were greater than during the same period last year; wheat freeze damage was slight, greening up occurred comparatively early; and the wheat seedlings took a turn for the better. This was manifested in the following ways: colonies had noticeably increased as compared with the onset of winter; the proportion of grades 1 and 2 seedlings rose, and the proportion of grade 3 seedlings fell.

At the present time there are also some disadvantageous factors for the winter wheat, and new problems may appear. One is that the current drought continues to develop. During April little rain fell over most of the northern winter wheat belt, and the threat from drought was very great. Weather forecasts predict a continuance of little rainfall in the north during May, so the job of fighting drought to protect the wheat will be a heavy one. Second, after mid-March many places experienced a springtime return of winter cold. Wheat jointing was delayed, and this led to late heading and a short in-the-milk stage, opening the prospect of damage from hot dry winds. Third, in most areas of the Chang Jiang and Huai basin, too much rain fell during May, and there was too little sunshine, making easy damage from stagnant water and wheat scab. In addition, in most places this year, individual wheat plant development was poor and ability to withstand damage from disaster weakened, which hurt prospects for increased yields. Fourth, wheatfield care was very uneven from place to place.

Winning of a bumper wheat harvest this year will still be a very arduous task. Given the local wheat growth situation and existing weak links it will be necessary to adapt general methods to local situations, to the seedlings, and to the time in an intensification of late stage wheat care. Northern wheat growing areas will also have to center field care around combat against drought through watering of the wheat. It is necessary to make full use of all water sources, do an effective job of pump well management responsibility systems, increased benefits derived from irrigation, and make sure to water the wheat during the in-the-milk and full ripening stages. Secondly, action will have to be taken so the wheat can withstand hot dry winds. In addition to watering in advance of the hot dry winds, spraying with potassium dihydrogen phosphate can also be done. Not only can potassium dihydrogen phosphate augment the supply of phosphate and potash that the wheat needs for growth during the late stage, but it can also play a role in strengthening the wheat's ability to withstand disaster. Southern wheat growing areas should give attention to cleaning out ditches and draining water to prevent water stagnation. Reports tell of outbreaks of powdery mildew and wheat scab, and army worms may also develop. Disease and insect pest monitoring and reporting work has to be intensified so that timely prevention and control can be done. In short, all prefectures should seize the opportune time to improve their production responsibility systems, to improve their level of scientific care, and use every available means to win a bumper wheat harvest.

'RENMIN RIBAO' STRESSES WATER-SOIL CONSERVATION

HK271327 Beijing RENMIN RIBAO in Chinese 24 Jul 82 p 2

[Commentator's article: "Resolutely Stop Those Acts That Undermine Water and Soil Conservation"]

[Text] The story of Haojialing production brigade of Zhongyang County in Shanxi Province, which reclaimed wasteland on steep slopes by ruining forests and grasslands is really startling. Zhongyang County was an advanced unit in preventing soil erosion in the mid-1950's. However, today, more than 20 years later, certain brigades of this county have gone so far as to seriously undermine water and soil conservation, and thus have destroyed in 1 day that which was achieved with painstaking efforts over years. The facts of the Haojialing brigade case tell us that we can no longer be indifferent to those practices of destroying vegetation which are occurring in quite a few places at present, gaining a little bit of profit at the expense of upsetting the ecological environment in which mankind is living is in fact a practice of killing the goose that lays the golden eggs, or rather, a practice of drinking poison to quench thirst. We must resolutely take measures to stop these acts that undermine water and soil conservation, and protect and improve the existing vegetation cover.

Destroying vegetation cover will give rise to serious consequences. This is common sense and is known by many people today. More than 100 years ago, Engels clearly pointed out, "In order to get more farmland, the people in Mesopotamina, Greece, Asia Minor and other places felled all forests. Nevertheless, contrary to their expectation, all these places have become barren land today, because they eliminated all the forests there by thereby eliminating all centers which collect and store water." Today, we need a good ecological environment as we are carrying out the construction of the "four modernizations," which includes the modernization of agriculture. What modernization can we expect if we just let the land which breeds every living thing continually suffer destruction?

"The regulations of water and soil conservation work" recently promulgated by the State Council, definitely provided that water and soil conservation must be strengthened, and that denuding forests and reclaiming wasteland on steep slopes by ruining forests and grassland are strictly prohibited. At present, one of the most important tasks for our leading organs at various levels, in particular the leading cadres in mountainous regions, is to conscientiously implement the "regulations," thoroughly carry out propaganda and education, and enhance the understanding of the vast number of cadres and the masses on the perniciousness of water and soil erosion and the importance of water and soil conservation. Various localities must promptly formulate detailed provisions for implementation and rules and regulations for concerned villages so as to more efficiently protect water and soil conservation facilities from being destroyed. We must adopt correct policies and measures to mobilize the initiative of the vast number of cadres and the masses. All units and individuals taking the initiative in protecting forest vegetation and reasonably utilizing water and soil conservation facilities for developing production should be encouraged and supported, and be rewarded with substantial economic benefit. Those who damage water and soil conservation facilities to seek personal and partial interests must be penalized economically. We must enforce the law and discipline, and seriously deal with those lawless elements who knowingly and seriously undermine water and soil conservation and refuse to mend their ways despite repeated admonition. We must resolutely stop people from continuing to cultivate crops on those steep slopes which are easily susceptible to soil erosion, and order them to replant trees and grass and take the responsibility of taking care of the planted seedlings. We must show to people the fact that seeking profit by undermining water and soil conservation can only be harmful and will never work.

In order to properly promote water and soil conservation, and terminate once and for all those activities of wantonly reclaiming waste land and undermining the ecological environment in mountainous regions, we must keep on reforming the agricultural economic structure in these regions. We must proceed from the overall situation, rationally arrange grain production and avoid blind development. In the past, mountainous regions used to export mountain products and import grains from the plains. Today, this historical barter relationship no longer exists in quite a few places. At present, the people in many mountainous regions have to solve the problem of grain supply by themselves. They plant grain crops on the hills. This causes serious water and soil erosion on some hillsides with steep slopes. However, at the same time, more farmland is used to cultivate industrial crops and the area of grain fields is constantly reduced in some plain regions which are suitable for grain planting. As grain producing areas fail to supply more grain, mountainous regions which are unsuitable for grain planting cannot help but reclaim wasteland and produce grain themselves. We must actively change this unreasonable situation step by step and in the light of the overall situation, give full play to the strong points of mountainous regions and grain-producing areas, conscientiously develop agriculture and a diversified economy according to the local conditions, and thus shape a healthy cycle of production and ecology.

NEED FOR IMPROVED HYBRID RICE VARIETIES UNDERSCORED

Fuzhou FUJIAN RIBAO in Chinese 2 May 82 p 2

[Article by Li Senhui [2621 2773 1920], Rice, Wheat and Barley Institute, Provincial Academy of Agricultural Sciences: "Improve Paddy Rice Breeding Work"]

[Text] Fujian Province is facing a problem of increasing grain output with all possible speed. There are two ways of solving this problem as follows: One is to expand the growing area, and the other is to increase yields per unit of area. The province's population is large relative to the amount of land requiring that the land be extremely cherished and that every available means be used to guarantee the area planted to grain. However, of even greater importance in increasing grain output is efforts to increase yields per unit of area. For improvement of rice output from the area being farmed, one good method is selection of fine varieties.

Since founding of the Chinese People's Republic, Fujian Province has done no small amount of work in the breeding and promotion of fine varieties. Rice yields per unit of area have risen from 196 jin in 1949 to 537 jin in 1980, a remarkable result. But how can we continue to hold fast to this crux of breeding and promoting fine varieties in the future?

One way is to define the direction of major attack. Today the peasants urgently demand that we breed high yield disease resistant varieties. Right now the greatest problem with the province's rice varieties is poor resistance to disease, which damages increases in yields. Rice blast and bacterial blight are great enemies of rice production. Last year damage to the early crop caused by rice blast was extremely serious, and most red strain varieties are particularly susceptible to disease. This makes the peasants lose confidence, and this raises an extremely grave problem for our scientists and technicians, namely how to breed with all possible speed new high yield disease resistant varieties. Some places have already bred new varieties that offer hope, and this is very heartening. But these new varieties will certainly have to undergo strict evaluation, and cannot be blindly promoted for cultivation. Some places are currently completely down on red strain varieties and tend toward indiscriminate use of unevaluated new varieties. Every jurisdiction should be alert to this.

Second, the situation of careless production of hybrid seeds has to be corrected. During the past year or two, many cadres and commune members have reported that "hybrid rice is mongrelized and no longer fine." Why is this? In terms of the hybrids per se, problems exist in the selection and breeding of fine combinations, but the fundamental reason lies in careless production of hybrid rice seeds. Right now in many communes and brigades, seed production is done by individual households or is scattered throughout a production team. Because both seed production techniques and conditions for separation are poor, the seeds produced are not pure, so the situation of "mongrelized and not fine" has become serious. It is recommended that "counties should breed and counties should develop," or else "counties should breed and communes develop" to assure quality and overcome the problem of "mongrelized and not fine." In addition, careful attention should be given this work.

Third is the need to make the most of existing technical forces to organize a concerted attack. The province currently has quite a number of units and people able to do the scientific and technical work of developing seeds. However, these personnel are widely scattered; additionally equipment is poor and funds are short making it impossible to meet the needs of research and production. High level leadership units should strengthen leadership to organize these forces to conduct a concerted attack, to solve some real problems, and to change the former backward situation of engaging in seed production with "a hoe in one hand and a basket of manure on a shoulder pole."

INCREASING RICE YIELDS IN LOW, INTERMEDIATE AREAS VIEWED

Fuzhou FUJIAN RIBAO in Chinese 2 May 82 p 2

[Article by Lu Haoran [4151 3185 3544], professor, Fujian Academy of Agricultural Sciences: "Exploit Production Potential of Intermediate and Low Yield Areas"]

[Text] What should the focus of Fujian Province's grain production be? I feel that exploitation of intermediate and low yield area's production potential fits the principle of small investment, quick results, and high benefits. The province's intermediate and low yield areas account for more than two-thirds the cultivated land area. Investment in areas with yields of 400 or 500 jin or 600 or 700 jin per mu holds an increased yield potential, a more rapid results potential, and a higher benefits potential than investment in areas that exceed "double goals" or double 1,000 jin in a year. Take fertilizer as an example. Fertilizer utilization rate and benefits in increased output per jin of fertilizer decrease as the amount of fertilizer increases. If each jin of ammonium sulfate can increase paddy yields by about 5 jin on an infertile field, on a fertile field it will increase yields by only 2 or 3 jin, a difference of almost 100 percent. This becomes a matter of "answering a genuine need," or "making perfection more perfect." Of course, what constitutes high, intermediate, or low yields is relative and changes as a result of development. High yields can always become higher yields. Use of limited financial, material, and human resources to get optimum economic benefits is an extremely important strategic matter.

Attention to intermediate and low yield area production requires adaptation of general methods to local situations and the promotion of effective technical measures, including traditional practical experiences and both domestic and foreign scientific achievements during the past several decades. A few examples are provided as follows: (1) Under guidance of state plan, adaptation of general methods to specific situations for a gradual restructuring of the agricultural structure of farming, forestry, livestock raising, sideline occupations, and the fishing industry, equitable crop patterns, and sensible matching of varieties. For example, when rice is grown in the deep and sodden fields at the entrance to mountain areas, it is prone to remain in the vegetative stage and to lodging; output is not high and consideration should be given to converting the fields to fish ponds with concurrent growing of lotus, duckweed, water cabbage, or such livestock feeds. Double crops of rice in high mountain regions produce inconsistently high yields, and it might be better to change to the growing of a single crop of intermediate rice (or hybrid rice) plus one crop of potatoes. (2) Farmland capital construction centering on harnessing of water and soil improvement. Low yield fields produce low yields because they are arid, waterlogged, cold, leached, sodden, infertile, clayey, sandy, or acidic, so the cure should fit the ailment, and disadvantageous factors should be eliminated to improve agricultural production conditions. But there should be no practice of formalism and no making of so-called "small, artificial plains." Genuine effectiveness should be the goal in a combination of the long term and the short term, with medium and small projects predominating, and with self-reliance predominating for equitable use and expansion of the investment of peasant labor. (3) A combination of fine varieties and fine methods so that fine methods will translate into reality the possibilities for increased yields of fine varieties. One does not necessarily have to promote fertilizer tolerant varieties in intermediate and low yield areas, but rather one should promote varieties of particularly wide adaptability that economize on use of fertilizer. (4) Improvement in distribution and use of fertilizer. In low yield and grain producing areas, additional care should be given fertilizer distribution because high yield areas or economic crop areas get fairly large bonus sales of chemical fertilizer. In mountain areas, the lack of phosphate and sulfur [sic] is fairly serious and soils are acidic for the most part. More superphosphate, potassium sulfate, gypsum, lime nitrogen, and lime should be distributed. In applying them, the past practice should be changed whereby much was applied early in the season and little applied late in the season, and whereby much was applied to nearby fertile fields and little applied to distant infertile fields. Use of farmyard manure on infertile fields brings fairly great benefits. Delayed action phosphate fertilizer is used on pulse crops and green manure crops, the phosphate increasing the action of the nitrogen; and quick-acting phosphate fertilizer is used on seedling fields or around seedling roots. It is recommended that ammonium carbonate, which readily volatilizes, be applied deeply in pellet form. In short, fertilizer should be distributed and applied on the basis of results of soil surveys, scientific testing, and production practice, and in accordance with the land and crops on which it is to be used so that limited fertilizer will bring greater benefits in increased output. (5) Use of comprehensive measures to prevent diseases, insect pests, and weed pests though use of disease and insect pest resistant varieties and wetland and dry land crop rotation. (6) In mountain areas where there is much land relative to population, and where a shortage of workforces exist for summer harvesting and planting, special attention should be given to improving the labor productivity rate. Priorities should be established in mountain regions for places where farm machines for plowing, planting, harvesting, hauling, and drying will be promoted.

Serious attention should go to study of agricultural science and technology. One of the main reasons why many intermediate and low yield crop production area outputs have fluctuated without rising has been careless farming and backward techniques, so study of agricultural science should be made a matter of importance. Forces should be organized for a concerted attack on key problems requiring scientific study to produce results rapidly in order further to develop agricultural production in high, intermediate, and low yield areas.

PROVINCIAL STATE FARMS' 1980 PROFITS REVEALED

Fuzhou FUJIAN RIBAO in Chinese 21 May 82 p 1

[Article: "Fujian Province's State Farms Profited Much Last Year. Economic Benefits Continued To Increase This Year. Early Quarter Production Situation Good"]

[Text] Last year the state farms in Fujian Province racked up profits once again on top of the profits of the 2 previous years. Profits amounted to 8.17 million yuan, a 23 percent increase over the previous year, making last year's profits the highest of the 3 years. This situation was presented by the recently convened state farm work conference.

Last year Fujian Province's state farms scored remarkable economic results. Except for a slight reduction of grain output occasioned by a downscaling of acreage and damage from natural calamities, economic crops, the livestock industry, and industrial sideline occupations all saw remarkable increases in output and earnings. The number of profit making enterprises increased from 86 in 1980 to 95 in 1981. This was 75 percent of the total number of enterprises. Losing enterprises fell by 10 from 1980. Tax revenues surrendered to the state in 1981 amounted to 6.85 million yuan, making it an all-time high year. All enterprises retained some award funds and increased employees incomes out of profits. They also withheld some funds to run employee dormitories, hospitals, schools, and such welfare endeavors. The material and cultural livelihoods of farm employees saw obvious improvement.

Provincial State Farm and Land Reclamation Bureau leadership comrades said, in the course of giving a briefing on experiences in scoring achievements, that prominence was given to two tasks last year. One was the stabilization and perfection of production responsibility systems; the other was readjustment of the internal structure of enterprises. While stabilizing grain production, they strove to develop economic diversification. Right now the production situation in state farms throughout the province is very good. In the growing of early rice, peanuts, soybeans and tobacco, plans handed down by the province have been fulfilled.

HENAN

BRIEFS

WHEAT OUTPUT, PROCUREMENT--Overcoming a severe natural disaster unusual since the establishment of the PRC, Henan Province reaped a bumper wheat harvest this year, with a total output reaching 22.7 billion jin. Compared to the bumper harvest year of 1981, this is an increase of 470 million jin, a historical record once again. By 8 July, Henan Province had procured 3.84 billion jin of wheat, and overfulfilled the summer grain procurement quota by 400 million jin. [Beijing RENMIN RIBAO in Chinese 13 Jul 82 p 1]

ISSUANCE OF WATER-USE PERMITS BOOSTS AQUATIC PRODUCTION

Huaiyin Prefecture Leads Way

Beijing RENMIN RIBAO in Chinese 11 May 82 p 2

[Article: "Huaiyin Prefecture Begins Work of Issuing Water-Use Permits"]

[Text] Huaiyin Prefecture in Jiangsu Province has begun the work of issuing permits for the use of collective surface water in rural people's communes. On the basis of delimiting the water belonging to the three levels--commune, production brigade, and production team--it has transferred water use rights from the collective to specialized brigades, specialized teams, specialized households, or individual commune members, thereby stimulating the enthusiasm for breeding fish on the part of the collective and the individual commune members.

Located on the lower reaches of the Huaihe River, Huaiyin Prefecture has a vast amount of surface water; and there are 1.6 million mu of water in which fish can be bred and aqautic economic crops grown. In the past, the rights to use some of the water were not clear, and the water resources were not fully used. In 1981, only a little over 800,000 mu were used for breeding and growing throughout the prefecture. After there was established in agriculture the responsibility system of contracts and linking output to remuneration and there was obtained a fairly large development in production, the agricultural problem of aquatic products backwardness, which created unclearness about water use rights, became more prominent. Last year, the Nanguangdang Commune in Shuyang County, by improving its management and administration of water, effected a big change in its situation. The commune delimited its over 1,700 mu of water surface as follows: over 80 mu to be managed by the commune, over 200 mu to be managed by production brigades, over 1,300 mu to be managed by production teams, and 78 mu of odd stretches of water surface to be privately owned and managed by commune member households. Afterward, by means of contracting out collectively managed water, the commune further delimited the use rights to specialized brigades, specialized teams, and specialized households, and this fundamentally changed the past situation in which "the collective had water but did not use it for breeding, and the masses thought of breeding but had no water." In this one year of breeding fish on ponds on the 1,700 mu of water surface, the total output of fresh fish was 350,000 jin, which brought in over 240,000 yuan of income. After summing up the experiences of Nanguangdong Commune, the Huaiyin Prefectural CCP Committee decided to begin the work of issuing water surface use permits throughout the prefecture.

First the party committee carried out experiments in this regard at Xuyi County. After gaining experience from the experiments, the committee started this work at the beginning of this year in 13 counties and cities. The main method was to carry out investigations of water surface resources, measure the water surface, confirm the limits, and, based on the history of distribution and the present situation, suit measures to local conditions and determine what water surface belonged to each of the three levels--production team, production brigade, and commune--and then, one by one, registered these limits in official books. Under the premise of the water surface proprietary rights generally not being changed, the committee gave out contracts for the use of collectively managed surface water to specialized brigades, specialized teams, and specialized households. After determining the profit distribution, the county people's government issues surface water-use permits, so that the water use rights will certainly not be changed for several years. The profits on water surface turned over by the collective for the commune to manage for their own personal needs go to the individual commune members; with water-use permits being issued by the county people's government to commune members, the proprietary rights of commune members households will not be changed for a long period of time.

In order to guarantee that the commune members, after being given the water-use permits, will effectively organize production, Huaiyin Prefecture stipulated that, after being issued the permits, the normal production activities and the proper economic interests of the users are to be protected by state laws, which no one can violate. Under the guidance of state and collective plans, the users have the right to manage the water on their own initiative and have the right to carry out some capital construction beneficial to the development of aquatic production, and to engage in planting, breeding, and other overall management activities. The rural regulations and civil agreements drawn up under the collective responsibility system educate the commune members not to steal, blast, or poison fish, and do not permit arbitrary equalitarianism and indiscriminate transfer of the aquatic products of fish-breeding households, thereby protecting the economic interests of the commune members. However, the water users may not transfer their rights, let out the water, buy or sell their rights, or fill up the water with earth; and water in which there has been no breeding or planting for the period of 1 year will revert back to the collective and other arrangements will be made for it.

According to statistics, permits have now been issued for the right to use over 280,000 mu of water in the prefecture, accounting for about 35 percent of the water for which permits should be issued; the counties of Xuyi, Siyang, Suqian, and Hongze, which made fairly rapid progress, have already finished the work of issuing water-use rights permits; and commune members of over 20,000 households, specialized teams, and group leaders have water-use permits affixed with the county government stamp.

As of the first part of April, throughout the prefecture spring breeding of fish was being done on 400,000 mu, an 11 percent increase over that of the corresponding period of last year; 150 million fish of various kinds were being bred, a 25 percent increase over that of the corresponding period of last year; and aquatic economic crops such as reeds, water chestnuts, lotus roots, and Gorgan fruit had been planted or sown on over 100,000 mu, an increase of 71 percent over that of the corresponding period of last year.

Short Commentary

Beijing RENMIN RIBAO in Chinese 11 May 82 p 1

[Article: "Important Measure for Developing Freshwater Breeding Enterprises"]

[Text] In Huaiyin Prefecture, Jiangsu Province, the issuing of fixed rights permits for use of the collective's water surface has aroused the enthusiasm of the collective and the commune members. Throughout the prefecture in spring, the number of fish bred rose 11 percent over that of the corresponding period of last year, and the acreage on which various aquatic economic crops were planted and sown rose by 71 percent over that of last year. This was a good experience in accelerating the development of freshwater breeding enterprises.

Currently, the water surface in some localities in the rural areas cannot be fully utilized and the development of freshwater breeding is not fast. The main reason for this is that the right to use the water surface is not clear. "Everybody tries to obtain water surface but nobody uses it for breeding." In places where the production responsibility system has not been put into effect, "the collective has water surface but does not release it for breeding, and the masses think of breeding but do not have the water surface for it"; and in some places where the production responsibility system has been established, because the time limit for using the water surface has not been made clear, the masses worry that they will not be able to use it for breeding for a long period of time and thus are unwilling to put much work and money into the breeding, so that the potential of the water resources cannot be fully brought out. On the basis of delimiting the water jurisdiction of communes, production brigades, and production teams, Huaiyin Prefecture did a good job of issuing water rights permits, assigning water rights for fairly long periods of time to specialized brigades, specialized teams, specialized households, and individual commune members, thereby stabilizing both the policy and public feeling. This is an important premise for arousing the enthusiasm of communes and production teams and of individual commune members, for exploiting and using water resources, and for developing aqautic production. By getting this good a grip on breeding, the masses' enthusiasm is aroused and freshwater breeding production can be developed fairly quickly. With regard to investment in aquatic production and the popularization of the science and technology of aqautic production, its effect is to get twice the result with half the effort. Developing aqautic production, as is the case with engaging in other enterprises, cannot be separated from the masses' enthusiasm. Huaiyin Prefecture's issuing of water surface rights permits means that the water users have the right to act on their own initiative in managing the water, so that the comprehensive management of the planting and breeding in the water can be carried out and so that, proceeding from the long-range goal of management, capital construction of the water surface can be carried out; the water users get more profit from putting out more work, the economic results are protected by law, and the income of the commune and the production team is increased, thereby organically combining the unified management of the collective with the independent management of the commune members.

TRADITIONAL SKILLS USED TO BOOST SOIL PRODUCTIVITY

Beijing RENMIN RIBAO in Chinese 6 May 82 p 1

[Article: "Improving Soil Fertility and Lowering Agricultural Costs"]

[Text] Since last winter, Jiangsu Province's Suzhou Prefecture, which possesses rich traditional agricultural skills and a fairly high level of farming, has made a point of restoring and developing traditional agricultural skills. A set of measures for output increases, which had been formed over many years in the past, have begun to be applied fairly well at each production link. Last winter, the acreage of wheat, barley, and oats throughout the prefecture under irrigation by water, river, and silt reached over 85 percent; this year there occurred a high tide of organic manure collection and fertilizer making that had not been seen for several years, and by the end of March on every mu of paddy rice there were 62 dan of accumulated grassy pond silt.

Suzhou Prefecture is one of China's key commodity grain bases. The peasants there have very rich experience in effectively utilizing land productivity and natural conditions. The output of grain and other agricultural crops is relatively high. In the past 2 years, some people thought that to modernize agriculture it was not necessary to bear hardships and stand hard work and that crop cultivation could be done by "applying chemical fertilizer and irrigating with ammonia water." Some traditional agricultural skills and production experiences were gradually neglected. In some places, the amount of organic fertilizer used became less and less, the amount of chemical fertilizer applied grew and grew, and agricultural costs rose higher and higher.

The Suzhou Prefecture CCP Committee and the prefecture's administrative office concluded that if this year's grain production was to be raised, there certainly must be displayed a spirit of hard struggle, the traditional experiences accumulated for a long time by the broad masses of peasants must be applied, costs must be lowered, results must be improved, and organic agriculture must be restored and developed. The prefecture vigorously popularized the experience of Taoyuan Commune, Wujiang County, in the mutual promotion of grain, silkworm, and animal husbandry undertakings, thereby improving people's knowledge of organic agriculture. For many years, Taoyuan Commune has raised a large number of pigs, sheep, and rabbits, has collected grassy pond silt, has returned stalks to fields, has put aquatic plants in suitable places for growth, has transported refuse from cities and towns and mixed it with fertilizer, and has applied relatively large amounts of organic fertilizer to every crop on every mu, thereby nurturing and fertilizing the land. Although the commune suffered natural disasters in 1981, its grain output still rose. By contrast, in some places much chemical fertilizer is used, the amount of organic fertilizer has decreased, land productivity has fallen, the resistance power of crops has weakened, and plant diseases and insect pests have become a serious problem, thereby adversely affecting output. This contrast has heightened people's understanding.

So that the work will be done well, the Suzhou Prefecture CCP Committee and the prefecture's administrative office have taken practical measures at every stage of production. For example, in February of this year, an on-the-spot meeting on collecting manure and making fertilizer was held in Fengqiao Commune, Wuxian County, which mobilized the great number of cadres and masses to effect an upsurge in collecting manure and making fertilizer. The administrative office designated March as a month for collecting manure and making fertilizer. Of the 53,000 production teams in the prefecture, every day over 48,000 teams are engaged in manure collecting and every day, at a steady rate, about 50,000 manure-collecting boats set out. In this way, the rate of manure collection was greatly accelerated, and everywhere on the prefecture's verdant fields there is grassy pond silt. There are fairly many cities and towns within the boundaries of Suzhou Prefecture, and this year the energy displayed by peasants in going into cities and towns to collect refuse to be mixed with fertilizer has been remarkable.

IMPROVEMENT OF SEED PURIFICATION STANDARDS DISCUSSED

Nanjing XINHUA RIBAO in Chinese 20 May 82 p 1

[Article: "Strive To Improve Purification Standards for Field Crop Seeds"]

[Text] Purification of field crop seeds is a basic task in seed work that has an extremely great bearing on development of agricultural production. Since the Third Plenary Session [of the 11th Party Central Committee], throughout the province fairly serious attention has been given seed purification. A lot of work has been done and definite achievements have been made. Throughout the province the fine variety area of the eight major crops has expanded rapidly for a virtual growing of little but fine varieties. Simplification of crop varieties has also been fairly evident, and extent of purification has also increased. Nevertheless, substantial unevenness exists in seed purification standards. For some crops the fine variety area is small and extent of purification is not high. In some places there are many varieties of the same crop and seeds have become mongrelized, the mongrelization now reaching serious proportions. In other places management of varieties and construction of seed bases require further improvement. The existence of these problems attests that the present state of seed work does not meet current requirements for the development of agricultural production, and that a good job of seed purification must be done at once.

Development of a socialist economy requires concern for economic benefits. In order to increase economic benefits from seed work, a good job of seed purification has to be done. Jiangsu Province's cultivated land area is small and grain, cotton, and edible oil output quotas are heavy. To insure a certain speed of agricultural growth, one cannot pin one's hopes on expansion of the cultivated area. Most important is reliance on increases in yields per unit of area, and increase in yields per unit of area requires not only devoting efforts to the culturing of crops, building fertilizer capacity, and improving the soil's physical and chemical properties, but even more important is to do something more about seeds. If we carry out a general purification and rejuvenation of grain, cotton, and oil bearing crop seeds, and replace field seed plans, even figuring on the basis of a fairly low increase in yields, the province's grain output could be increased by 2 billion jin, and economic income increased by 200 million yuan. Ginned cotton output could be increased by more than 900,000 dan for an increase in earnings of 150 million yuan; and oil bearing crops could be increased by 550,000 dan for an increase in earnings of almost 30 million yuan. These are output and earnings increases figured solely on the basis of increased seed purity. Were output increases from fine varieties factored in, even more impressive figures would result.

Enthusiasm for scientific farming is very high in all communes and brigades and among the peasants in the farflung rural villages in order to increase output and earnings, and the demand for fine varieties is extremely urgent. They want not only new varieties with high yields, fine quality, early ripening capabilities, strong resistance, wide adaptability, and all around fine properties, but they also demand seeds with a high degree of purity and high quality. Consequently, it is extremely important that we summarize experiences, absorb past lessons, and place on the daily agendas of leaders concerned at all levels the job of purifying fine variety field seeds.

Seed work has many aspects, as for example management of varieties and regionalization of distribution, purification and rejuvenation and replacement at fixed times; building of seed bases and carrying on specialized production; and organization of the production, state procurement, and marketing of fine varieties, etc. However, improvement of fine variety purification standards for field crop seeds is a key problem in seed work. This is the bottom line in judging and checking on all kinds of seed work. If this key problem is to be taken firmly in hand and a firm stand taken on this bottom line, the thinking of some comrades that values doing things but slights breeding, that values introducing things but slights rejuvenation, that values using them but slights caring for them will have to be overcome. Seed units at all levels should centrally manage the introduction of new varieties. In the production of new varieties, they should follow a sequence of "experiments at two levels; prefecture examination; and centralized examination and verification, assigning a name, and promotion by the province," with planting being done in designated spheres. Varieties that have not undergone testing should not be presented for examination, and varieties that have not been examined and approved or that have undergone examination and been found wanting may not be promoted at will by any unit or individual. When varieties are introduced, scientificness is desired with less blindness. Replacement of varieties requires positiveness, prudence, thoroughness, and precision. For planned propagation and planned replacement, both fine varieties and fine methods should be promoted together so as to avoid large ups and downs and to guard against blindly seeking after something new.

Sensible simplification of varieties is a major step in bringing about seed purification. Therefore from the foundation of a variety survey and in combination with production requirements of all jurisdictions, a comprehensive inventorying and appraisal should be conducted to decide which varieties should be developed and promoted, which ones may be used transitionally, and which ones should be rejected. In simplifying varieties, peasant varieties should be identified and matching of varieties should be rational to preserve a relative stability.

Impure seeds of fine varieties cannot produce their full potential for increased yields. Therefore, comprehensive launching of purification and rejuvenation work is an effective measure for insuring the variety characteristics of fine varieties, for preventing mongrelization and deterioration, and for lengthening the number of years a fine variety may be used. Purification and rejuvenation work requires a division of labor. Purification of hybrid parent pairs is taken care of by seed departments at the provincial and prefecture levels. Purification of conventional varieties is done mostly by counties, by state stock (or fine) variety farms, and my county agricultural institutes. Production units having requisite conditions may also be selected to establish bases by special arrangements for purification and rejuvenation. Many years of experience show that when individual communes and brigades engage in purification and rejuvenation, setting up their own small but complete systems, not only is there a duplication of work that produces a waste of manpower, material, and financial resources, but as a result of problems in technical standards and management, quality of purification and rejuvenation is also likely to be impaired. Vigorous launching of mass selection and withdrawal of seeds is also an effective way to prevent mongrelization and deterioration of seeds. All jurisdictions should use various ways to mobilize the masses to select and withdraw seeds in each crop selection season. Places practicing the contracting of work tasks or production to individual households are to assign these seed selection tasks to households. In addition, there is no need to set up fixed seed bases or to engage in specialized seed production. Strict attention to all around quality management, vigorous promotion of machine selection of seeds, genuine strengthening of seed inspection and quarantine work so that every link from seed production to procurement, to processing, to transportation, to packaging, to storage, and on to marketing meets set quality standards will insure seed purity.

BRIEFS

SHUYANG COUNTY SUMMER HARVEST--Shuyang County in Jiangsu Province has achieved a bumper harvest of summer-ripening crops. The output of wheat, barley and naked barley totals more than 390 million jin, topping last year's record by some 140 million jin. The production of rapeseed was 10 million jin, double last year's output. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 2 Jul 82 OW]

FUNING COUNTY WHEAT PRODUCTION--Peasants in Jiangsu's Funing County reaped a bumper wheat harvest this summer with total output increasing by some 60 million jin over that of last year. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 5 Jul 82 OW]

SUMMER CROPS--Bumper harvests of summer crops have been reported in various localities of Jiangsu Province. Output of over 100 million jin of summer grain crops has been reported in Shuyang, Yixing and Wujin counties. [Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 6 Jul 82 OW]

SEED COMPANIES IN IRRIGATION DISTRICT IMPROVE WORK

Beijing RENMIN RIBAO in Chinese 8 May 82 p 1

[Article: "Counties in Ningxia's Irrigation District Vigorously Supply Seeds for Spring Sowing"]

[Text] The seed companies in 11 counties in Ningxia's irrigation district have vigorously improved seed supply work, and this year there has appeared a gratifying scene with regard to spring-sown crop seeds in which the seeds have been marketed quickly and their sales volume has grown. Now, of the seeds of improved varieties of spring wheat that the seed companies have in stock to satisfy needs, 7.4 million jin have been sold, over 10 percent of the wheat seeds required to be sold in the irrigation area.

This year the seed companies have set up additional seed supply points and seed distribution points in remote communes and production teams and in communes, production teams, and market towns where the population is concentrated, in order to supply close at hand improved seed varieties to the peasants.

In the past, before the peasants bought seeds they had to first go to grain depots and buy grain and then, with evidence of their grain purchase, they could buy seeds from seed companies.

This involved many procedures and was inconvenient. This year the system has been changed to one in which the masses directly exchange their grain for improved seed varieties and the price difference is offset by the equivalent in grain, thereby simplifying procedures. At the same time, in order to deal with the special feature that, after the responsibility system is put into effect, the peasant households purchase a smaller amount of seeds and sell more things at retail, with the concurrence of grain departments, a portion of the seeds is sold at a negotiated price.

NEW GRAIN MANAGEMENT SYSTEM ANALYZED

Xian SHAANXI RIBAO in Chinese 9 May 82 p 1

[Article: "Major Restructuring of Grain Management System. Beginning With This Year's Summer Harvest All Jurisdictions in the Province Will Begin a New Method Guaranteed for 3 years of Assignment of Sole Responsibility for State Grain Procurement, Marketing, Allocations and Transfers"]

[Text] Beginning with this summer's harvest, Shaanxi Province will institute assignment of sole responsibility for state grain procurement, marketing, allocations and transfers in a new method guaranteed for 3 years. The provincial government has asked all jurisdictions to take firmly in hand the implementation of this task, making sure that prior to the summer harvest assignment of sole responsibility for state grain procurement quotas is gradually implemented in production teams, work teams, and commune member households.

This major restructuring of the grain management system was decided on by the State Council. As compared with the former state procurement base figures, which were guaranteed to remain unchanged for several years, and procurement in excess of quotas guaranteed for a single year, this method is more advantageous in bringing into play both central government and local govenrment initiative, in promoting and enlivening grain dealings, and in improving administration and management of grain enterprises for greater economic benefits. It is also advantageous in stabilizing peasant burdens, and is both suited to and advances reform of the agricultural structure. Particularly, once assignment of responsibility for state grain procurement quotas has been instituted in production teams and commune member households and linked to assignment of responsibility for output, not only will the peasant masses know how much grain they are responsible for producing in any given year, but they will also know how much grain they will be responsible for surrendering to the state in any given year plus 2 years thereafter to bring about "knowing 3 years in advance" state grain procurement quotas.

In accordance with the management method approved by the State Council, figures for assignment of grain responsibilities in all jurisdictions will be based on actual state grain procurement, marketing, transfers and allocations during the previous several years in combination with changes during the next 3 years in the development of grain production, state procurement and marketing as determined through discussion and verification. Figures for assignment of responsibility for state procurement include state procurement base figures and excess procurement quotas. When production teams sign contract agreements with commune members, they should include within the scope of agreements output, variety, and state procurement base figures, and excess procurement quotas. Figures for assignment of marketing responsibilities include non-agricultural and agricultural marketing as well as grain formerly expended for special purposes by provinces. Figures for assignment of responsibility for inbound grain include regular inbound movement and grain expended by provinces for special purposes. Figures for assignment of responsibility for outbound grain are outbound figures from which grain for special use has been deducted. During the period of assigned responsibility, all grain remaining as a result of much procurement and fewer sales is to revert to each jurisdiction for its disposition. Should natural disasters or other reasons result in a grain deficit, solution will also be up to local jurisdictions themselves. Years of major calamities requiring provincial transfers of grain are to be subsequently repaid in full.

This year will be the first one for institution of assignment of grain responsibility. How equitably all criteria are implemented will be important for fulfillment of assigned grain quotas for the next several years and for a balance between supply and demand of grain in Shaanxi Province. Now the summer harvest is at hand, and the provincial government asks that all jurisdictions actively and painstakingly take firmly in hand the assignment of responsibility for grain quotas, particularly verification of state procurement quotas. With this as a starting point, after several years effort, Shaanxi Province's grain commodity rate will see fairly rapid increase to make a greater contribution to the building of the four modernizations.

TECHNIQUES FOR FINDING, TESTING, USING DESALINIZED GROUND WATER EXPLAINED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 6, 1982 p 2

[Article by Soil Fertility Institute, Shandong Provincial Academy of Agricultural Sciences: "Need To Exploit Shallow Depth Desalinized Ground Water"]

[Text] By shallow depth desalinized ground water is meant the layer of fresh water with low mineralization at a general 2 to 4 grams per liter found in a "desalinized layer" atop the highly mineralized underground saline water belt in alkaline-saline areas along the seacoast. By and large natural precipitation and human diversion of water for irrigation causes the highly mineralized water atop the highly mineralized underground saline water belt to undergo change and differentiation, gradually becoming fresh water, which can be substantially used in agriculture or as potable water for people and animals. This is a source of fresh water in saline-alkaline coastal areas that is of great utility.

The major means of locating freshwater and a shallow depth underground are two, as follow: One is use of the geobotany of the landscape (i.e., the distribution of plants on the surface) to analyze and determine the existence and extent of distribution of underground freshwater in saline-alkaline areas. For example, in areas close to the sea in Shandong Province, the ecological system is composed of plants that grow in saline soil, chiefly Huangxu [7806 3291], Suaeda maritima, and Chinese tamarisk, showing that the soil has a salt content above 0.5 percent and that a "freshwater layer" of fairly low mineralization has not yet formed atop the underground salty water belt. On the delta where the Huang He enters the sea, plants are mostly those of a natural oases ecological system, largely plants such as cogongrass [Imperata cylindrica], small reeds, and natural willow forests which show the degree of soil salinization and alkalinization to be slight and that rather good "desalinated water" water exists below ground. In state farm and land reclamation areas, the geobotanical landscpe is largely a farm; and plant ecological system composed of various kinds of farm crops. This shows a soil desalinization below 0.3 percent, and that atop the underground saline water belt a fairly good "freshwater layer" has formed. The geobotanical landscape is the basis for seeking underground freshwater at a shallow depth in a macroregion. The second means is comprehensive analysis and judgment based on topography, landforms, and soil texture. Generally speaking, on both sides of running streams, in old riverbeds, in lowlying land, and in agricultural irrigation zones, desalinization has occurred, the freshwater at a shallow depth being relatively concentrated and its degree of purity being rather good. In sections having fairly clayey soil, the extent of desalinization of underground desalinized water at a shallow depth is better than in areas of lightly textured medium soils and pulverized gravel soils. Results of prospecting done in clayey soil and pulverized gravel soil 500 meters distant from each other showed that in the clayey soil sections, the extent of mineralization of underground freshwater at shallow depth was 0.7 grams per liter, while the extent of mineralization of underground freshwater at shallow depth in pulverized gravel sections was 5 grams per liter. In searching for desalinized underground water at a shallow depth within a small area, it is necessary to watch distribution of soils of different textures.

Desalinated underground freshwater at shallow depth is characterized in the following ways: wide distribution in geographic space, distribution not very thick in vertical space, and buried at a shallow depth beneath the surface. In exploiting underground freshwater at a shallow depth, it is necessary, first of all, to determine the point at which the surface of the "freshwater layer" meets the surface of the excessively saline water layer. After taking water samples for testing to determine whether water quality is suitable for exploitation, hydraulic wells are sunk into the "freshwater layer" above the intersecting surface, and the water is then raised. When installing hydraulic pumps, one should be careful not to push pipes through the "freshwater layer" so as not to raise saline water to the surface. Three or four hydraulic wells per mu of farmland may be installed, and enough water may be raised from them daily to provide soil moisture to about 1 mu of land.

Before underground desalinized water at a shallow depth may be exploited for use, it must be evaluated for quality. Evaluation usually consists only of measuring salt content, with composition of the salt being measured when necessary. If the magnesium ion content of the water is high, it may cause diarrhea and should not be used as drinking water by people or livestock. Water quality standards for water used to irrigate plants usually require a salt content of less than 2 grams per liter. When fighting drought in order to sow crops, this standard may be liberalized somewhat. Results of experiments in the use of freshwater of different degrees of desalinization on the growth of wheat sprouts and seedlings has shown that when the salt content of desalinized water is between 3 and 4 grams per liter, it has virtually no adverse effect on the growth of wheat sprouts or seedlings. When salt content of desalinized water was 5 to 6 grams per liter, it seriously restricted growth of wheat sprouts and seedlings; however, if a way can be found to mix in a proper quantity of freshwater, such water may also be used. Where chemical testing conditions permit, the method used for evaluating water quality may be either the drying method or the electrical conductance measuring method. When chemical testing cannot be done, test methods using growth of seed sprouts and seedlings may be used. If culturing in desalinized water brings similar sprout and seedling growth as when distilled water or drinking water is used for culturing, this shows quality to be very good and it may be used. If seeds do not sprout or if they sprout but do not elongate, this shows the salt content of the water to be too high, making it unuseable.

Methods for finding and using formations of underground desalinized water at a shallow depth in saline-alkaline prefectures along the seacoast are also of reference value for the inland saline-alkaline prefectures of Heze, Liaocheng, and Dezhou.

STEPPING UP OF FLOOD PREVENTION MEASURES URGED

Jinan DAZHONG RIBAO in Chinese 16 May 82 p 1

[Article: "Early Preparations Against Flood Season by All Jurisdictions Is Requirement From Flood Season Prevention Conference Convened by Provincial Government"]

[Text] The Flood Season Prevention Conference recently convened by the provincial government required all jurisdictions to make active preparations against the flood season even while continuing to fight drought.

The conference noted that despite the current drought in the province, the flood season is about to arrive. According to forecasts, during this year's flood season, rainfall in the lower reaches of the Huang He will be somewhat greater than normal, and quite possibly southwestern Shandong and northern Shandong prefectures may experience unaccustomed amounts of water. In considering this year's flood season, one should stick to "better believe it will happen rather than believe that it won't." Preparations should be made against the eventuality that it will rain, and preparations should be made against the eventuality that the rains will be large, making good preparations for the worst while hoping for the best and being prepared just in case.

Overall requirements resulting from the conference's study of this year's flood season prevention tasks are as follows: Adherence to the principle that "prevention is the key, prevention being better than salvaging," with implementation of centralized leadership, level by level responsibilities, and attention given to mental, organizational, project, and material preparations, and to prudent management and bolstering of defenses so that, within existing project standards, there will be no breaking of reservoir dams or bursting of river dikes or waterlogging turning into a disaster. Countermeasures have to be readied against abnormal flooding, every available means used to assure safety during the flood season and to reduce damage.

In order to fulfill this year's flood season tasks, the conference required each jurisdiction to take firmly in hand the organization of inspections in advance of the flood season, and to gradually study and solve problems uncovered in the source of inspections. Hidden faults at the base of reservoir projects should be handled first. All dike openings, temporary dams, and high channels for water diversion should be handled within a limited period of time. Plains areas should put their drainage systems in order to assure smooth drainage. Along the shores of the Huang He, production dikes and obstacles to the flow of floodwaters in the river should be cleared away in accordance with regulations. Leadership should be strengthened and sufficient workforces transferred for projects for getting through the flood season that have been layed out. For hazardous projects that cannot be taken care of for the time being, emergency measures for safe passage through the flood season should be conscientiously instituted and guarding strictly done to insure safety. Cases of destruction of water conservancy projects must be strictly dealt with to bring about a resolute halt. For all Huang He, inland river, and reservoir water conservancy projects, a corps to guard against the flood season should be organized, its duties clearly stipulated, good training given it, and sufficient materials to protect against the flood season should be made ready. Urban flood prevention work should be strengthened. Streams for the discharge of urban flood waters should not be filled in, river shallows should not be occupied; there should be no haphazard digging or building done, garbage dumped, or wastes discharged that impede the safe movement of flood waters.

POINTERS GIVEN FOR GROWING OF STURDY RICE SEEDLINGS

Shandong NONGYE ZHISHI [AGRICULTURAL KNOWLEDGE] in Chinese No 8, 1982 p 7

[Article by Jin Liufu [6855 3966 4395]: "Technique For Breeding Sturdy Rice Seedlings with Tillers"]

[Text] The breeding of sturdy seedlings with tillers is an important way in which to increase rich output. Because a great amount of organic nutrients are stored within the bodies of sturdy seedlings with tillers, roots develop rapidly following planting, the number of new roots averaging 10.7 to 21.3 more in number than for seedlings with tillers. Greening up also occurs faster than for seedlings without tillers, growth of new leaves on individual plants averaging 2.8 to 8.3 more in number. Where the salt content of water in fields runs to 0.3 to 0.4 percent, the survival rate is four to five times higher. Tillers develop rapidly, the effective tillers being numerous and sturdy, with panicles numbering between 60,000 and 90,000 per mu, and ripening occuring between 2 and 5 days early. Yields increase by about a general 18 percent as compared with seedlings lacking tillers.

Mastery of four techniques is required in growing sturdy rice seedlings with tillers, as follows:

1. Fertility of seedling fields. Best is selection for use as seedling fields those plots that contain 1.5 to 2.0 percent organic material, 10 to 20 ppm quick acting nitrogen, and upwards of 10 ppm of quick acting phosphate. As base fertilizer, between 5,000 and 8,000 jin per mu of thoroughly composted organic fertilizer, 20 to 30 jin of ammonium sulfate, and 50 to 70 jin of superphosphate should be applied. Depending on seedling color and growth during the seedling growth period, additional dressing with 30 to 40 jin of ammonium sulfate should be given.

2. Small quantity of seeds grown. Experiments show that when seedling fields are sown at the rate of 50 jin per mu, the plant tillering rate is 74 percent. When 75 jin per mu are sown, the plant tillering rate is 54 percent. When 100 jin per mu are sown, the plant tillering rate is 40 percent, and when 120 jin per mu are sown, the plant tillering rate is less than 10 percent. Furthermore, the greater the quantity of seeds sown, the higher the tiller death rate after the seedlings grow. Consequently, a suitably small quantity of seeds should be sown on seedling fields. For early seedlings, between

70 and 100 jin per mu should be sown; for seedling propagation in moist conditions, between 50 and 70 jin per mu should be sown.

3. The layer of water should be kept shallow during the tillering period. At the four leaf stage, seedlings begin to tiller. By withholding water during this stage, seedling roots go down fairly deep and tillering is controlled; seedlings become hard to pull up. If the layer of water is overly deep during this time, the seedlings are prone to development of black root and seedling death. Experiments show that after the three leaf stage for seedlings, water should be maintained at a depth of 0.5 cun and no more than 1 cun. Fields should be regularly aired at night to promote tillering and growth of sturdy seedlings.

4. Use of chemical herbicides to eliminate weeds. Weeds compete with seedlings for sunlight and fertilizer and seriously impede seedling tillering. Chemical herbicides may be used to eliminate them. The specific method used is as follows: 1) Seedling field preparation in advance of sowing. Between 6 and 7 days in advance of sowing, 25 percent nitrofen at the rate of 1 to 1.2 jin per 40 to 50 jin of water should be applied. After the seedling bed surface has been sprayed, a layer of water should be maintained on it for 7 to 8 days. 2) Spraying of herbicide during the seedling stage. Between the 1 and 2 leaf per seedling stage, 20 percent propanil emulsion at the rate of 2 to 2.5 jin per 30 to 40 jin of water should be sprayed on leaves. In seedling fields heavily infested with sanlengcao [0005 4462 5430] and niumaocao [3662 3029 5430], misting may be done with 70 percent dimethyl-tetrachloride. Alternatively the two aforementioned herbicides may be mixed together and applied. When spraying leaf surfaces, a warm wind-free day should be selected. Fields should be aired for 1 day before and after spraying after which water should be maintained in the fields to a depth of 1.5 cun for 6 to 7 days to drown the weeds, after which normal irrigation may be recommenced.

SPECIFICATIONS PROVIDED FOR NEW COTTON VARIETY

Shandong NONGYE ZHISHI [AGRICULTURAL KNOWLEDGE] in Chinese No 9, 5 May 82 pp 27-28

[Article: Briefing on Cotton Variety Zhongmiansuo No 1"]

[Text] (1) Variety Origin. Zhongmiansuo No 10 cotton (formerly called Zhong 509] was bred by the Cotton Institute of the Chinese Academy of Agricultural Sciences in 1975 from the continuous selective breeding of 23 selected long fiber plants of cotton variety Shanmian No 1 followed by selection of natural mutants from the 23 strains.

(2) Characteristics and Properties. Plant heights for this variety are about 60 centimeters; plants are compact and tubular in shape. Fruiting branches stick upward; distances between nodes are short, and secondary fruiting branches produce large bolls. Zhongmiansuo No 11's main stem is fairly small; leaves are fairly thin; leaf color is light; individual leaves at the tops of plants stick straight up, and phototaxis is strong. Bolls are vently spaced at the top, middle, and bottom of plants; boll formation is strong; bolls are fairly concentrated, and the dropping rate for squares and bolls is low. Bolls are ovular, and average weight of individual bolls is about 5.5 grams; ginning outrun is about 35 percent; and seed numbers is 10-11 grams. This variety prefers soil with fairly good fertility and water conditions; it does not tolerate infertility; does not tolerate waterlogging; and will not withstand drought. Yet another major characteristic of Zhongmiansuo No 10 is early ripening, its total growing season being only about 114 days. When sown before 20 May to 5 June in south central Shandong and southwestern Shandong prefectures, its before frost cotton rate was better than 80 percent. Naturally, owing to differences in climatic and cultivating conditions in different places, the variety's growing season differs. For example, during the past 2 years when sown on 8 June in Linyi County, it had a total growing season of from 111-119 days, with more than 80 percent of its cotton being produced before frost. When sown on 5 June in Liaocheng County, its total growing season was 122 days. Planted on 6 June in Linqing County, its total growing season was 129 days and it produced 51.06 percent of its cotton before frost. Sown in Huimin County on 12 June, its total growing season was 123 days and it produced 29.15 percent of its cotton before frost.

(3) Yields. Experiments conducted at 12 sites in a farming system reform experimental area in the Huang He basin in 1980 produced yields of ginned cotton averaging 138 jin per mu, and yields averaging 114.52 jin per mu in 1981 to take first place in average yields per unit of area. Results of area testing of early ripening varieties in Shandong Province in 1981 were as follows: At four experimental sites in central and southwestern Shandong, ginned cotton yields averaged 136.4 jin per mu, 15 percent more than for Luzao No 1. At two experimental sites in northern Shandong, ginned cotton yields averaged 120.9 jin per mu, 12.2 percent less than for Luzao No 1. At four experimental sites in northwestern Shandong, ginned cotton yields averaged 126.3 jin per mu, 3.1 percent less than for Luzao No 1. At two experimental sites in Linyi and Liaocheng counties, when Zhongmiansuo No 10 was sown on 8 June and 5 June, ginned cotton yields averaged 108.3 and 159.2 jin per mu respectively, 41.4 percent and 5 percent more than for Lukang No 1.

(4) Fiber Quality. Measurements made in 1979 by the Beijing Municipal Fiber Inspection Institute showed quality standards for 32 count yarn in test spinning to be 2,700 fen [0433 ? pick]. Quality standards for test spinning of 32 count yarn at the Northern He'nan Cottin Spinning Plant in He'nan Province in 1980 showed a quality standard of 2,700 fen. Test spinning of 42 count yarn at the Jinan National Cotton Plant No 4 in 1981 showed a quality standard of 2,820 fen. Results of testing of physical properties in 1981 showed most fibers to have a length of 30.12 millimeters, the tensile strength of individual fibers to be 3.83 grams, a fineness of 6,793 meters per gram, and a breaking length of 26,190 kilometers (sic).

CORN, WHEAT INTERCROPPING TECHNIQUES EXPLAINED

Shandong NONGYE ZHISHI [AGRICULTURAL KNOWLEDGE] in Chinese No 9, 5 May 82 p 22

[Article by Mao Guizhang [3029 6311 4545], Yantai Prefecture Agriculture Bureau: "How To Arrive at the Time for Intercropping Corn"]

[Text] Proper timing of the sowing of corn when intercropping with wheat not only bears on whether or not summer corn yields will be high, but also bears on whether the following crop of wheat can be sown on time. It is necessary to adapt general methods to local situations and varieties and, in a spirit of concurrent concern about both the wheat and the corn, to arrive at a time for the intercropping of corn.

In Yantai Prefecture, the time for sowing corn for intercropping with wheat is arrived at on the basis of the factors given below.

One is to arrive at the intercropping period for corn by using the right time for the sowing of wheat to extrapolate forward the harvest time for the corn. For example, the right time for sowing the wheat is between 20 September and 5 October so the wheat will get between 650 to 700°C cumulative temperature before the onset of winter, and so the wheat seedlings will produce numerous tillers and sturdy seedlings to help it safely over winter. Extrapolating ahead from 15 September to get the time for intercropping means that corn varieties with a growing season of 120 and 100 days should be intercropped in Yantai Prefecture on 15 May and 8 June respectively.

Second is extrapolating ahead the time for intercropping corn by using the initial period of corn ear differentiation as the time to harvest wheat. During the period of common growth for wheat and intercropped corn, competition exists to obtain water, fertilizer, and light. When the corn enters the stage of ear differentiation, in particular, the competition between the two crops for fertilizer and water becomes more pronounced, and if there is a lack of water or sunlight, differentiation of the young ears may be impaired. Corn varieties with a growing season of 100 to 120 days have an initial ear differentiation period lasting 35 to 45 days. Consequently, the period of common growth for corn intercropped with wheat should not exceed this segment of time, i.e. the corn intercropping period should not exceed the initial ear differentiation stage.

Third, strength should be put to use and weaknesses avoided in weather conditions to turn disadvantages into advantages. Principal weather factors limiting corn production are the following: 1) Insufficient cumulative temperatures during the growing stage. Corn varieties with a 100-120 day growing season require cumulative temperatures totaling from 2,300 to 2,800°C over the growing season, but summer corn often does not get the full amount. 2) Failure of the period of naturally high temperatures to coincide with the period of high temperatures needed for corn to develop. During the period of flowering, pollination, in-the-milk, and kernel setting, average daily temperatures of 24-26°C and from 20-24°C are required. If they are too high or too low, corn pollination may be impaired and kernels small. 3) Waterlogging during sprouting and seedling stages. If within a period of 40 days after the corn has been planted a rainy season occurs in which the amount of precipitation is more than double that required by the young seedlings, sprout waterlogging and seedling waterlogging may occur. Thus, when figuring the intercropping season for corn, this factor has to be taken into consideration so as to take advantage of strengths and avoid weaknesses of the local climate and turn disadvantages into advantages.

On the basis of the overall balance of the foregoing conditions, Yantai Prefecture adapted general methods to local situations to use two intercropping periods and two intercropping methods. Huang County, Ye County, and some of the plains area of Zhaoyuan, where temperatures are rather high, summer waterlogging rather slight, and autumn cold comes rather late, used an ordinary intercropping method, by which is meant that at the time the wheat was sown, a distance of from 0.8 to 1 chi was left between rows for the intercropping of corn, and intercropping was done 15 to 20 days before the wheat was harvested (around 10 June). In the 12 counties and municipalities including Rongcheng, Wendeng, Rushan, and Haiyang, which are low-lying areas along the sea or along rivers, where temperatures tend to be low, summer waterlogging severe, and autumn cold arrives early, "2-4 plot" intercropping was used. By this is meant that wheat was sown in 4 chi square plots with plots 2 chi square being left next to them. Between 35 to 45 days before harvesting of the wheat, (around 10 May) two and a half rows of summer corn were intercropped. Inasmuch as the time of intercropping and intercropping methods suited local natural conditions, plus improvements in other methods, increases in corn yields were greatly advanced.

NEW CORN VARIETY CHARACTERISTICS, SEED PRODUCTION DESCRIBED

Shandong NONGYE ZHISHI [AGRICULTURAL KNOWLEDGE] in Chinese No 9, 5 May 82 pp 24-25

[Article by Cui Guangdian [1508 0342 7193] and Cui Qingyun [1508 1987 0061], Linyi Prefecture Seed Station: "Corn Variety, Shendan No 3"]

[Text] Corn variety Shendan No 3 was bred by the Shenyang Municipal Agricultural Institute in Liaoning Province in 1974 using inbred line "Zi 330" as the female parent and inbred line "Baihe 43" as the male parent to produce a single hybrid variety. In 1977, following examination and approval by the Liaoning Provincial Crop Variety Examination and Approval Committee, it was promoted to cultivation. In 1980 it was introduced into Linyi Prefecture for test planting. A brief description of this variety is given below.

Characteristics and properties: Plant height of 250-270 centimeters; ears located at around 80 to 90 centimeters. Bud sheaths on young seedlings are purplish red in color; leaves are slightly rippled; leaves total 19 in number; and plant shape is compact. Ears are tubular in shape and grow 20-24 centimeters in length. Kernels are yellowish white, are of the dent type, and ears contain 46 kernels in 18 rows, the per 1000 weight of kernels being about 400 grams, individual ears weighing about 300 grams. The growing season, when planted in spring, is about 130 days; when planted in summer, it is about 110 days. It is fairly resistant to large and small leaf spot, and to head smut. It is slightly susceptible to green withering.

Yields. In experiments conducted at a total of 10 test sites in 4 districts of Shenyang Municipality and in Xinmin and Liaozhong counties in 1975, yields averaged 1,322 jin per mu, 29.7 percent more than from control variety Danyu No 6. In demonstration experiments conducted at Dazhuxia Production Brigade in Chahe Commune, Linyi County in 1980, Shendan No 3 yields were 1,352.09 jin per mu, 13.15 percent more than for control variety Danyu No 6, and 11.55 percent higher than for Lusan No 9.

Essentials of farming and seed production. Shendan No 3 has moderate fertility and water requirements. It is suited for growing in poor soils and in oily sandy soils for moderate fertility. When grown where fertility and water conditions are bad and the soil is fairly poor, either wide row cultivation or intercropping with wheat produces definite increase in yields.

Planting density should be 2,800-3,200 stalks per mu (more produces susceptibility to green withering). During the period of vegetative growth, care should be taken to prevent and control corn borers and green withering. For seed production, when the female parent has three leaves on a stalk, the male parent should be sown, the ratio of rows being 2:4 or 2:6. When producing seeds through backcrossing, both female and male parents may be sown at the same time, or the male parent seeds may be dipped in bud stimulant and sown together with the female parent, row ratio being 2:6 or 2:8.

CSO: 4007/445

BRIEFS

NEW ANTIDROUGHT METHOD LIMNED--Dongdianhou Production Brigade in Longquan Commune, Mouping County took advantage of the large number of ravines and streams locally to dig ditches in the bottoms of streams, wall them with masonry, and raise water. This was an antidrought project for raising the underflow to the surface, which effectively solved problems in fighting drought during seasons when the streams dried up. The masses called them "reclining wells." The specific way of making reclining wells is as follows: Dig a 20 meter long, 5 meter wide, 3 meter deep corridor across the river bed and then wall the corridor with rocks, adding stone slabs or concrete slabs across the top. Atop the concrete slab add water filtering sand and stone to a depth of about 1 meter to produce a well that looks at though it is reclining on its side. Then wall up a verticle shaft from which water can be drawn at one or both ends of the reclining well, and use a water pump to pump the accumulated water in the reclining well to the surface to irrigate the fields. Tests show such a well can raise more than 100 cubic meters of water per hour. The infiltration section of such a reclining well is large. Both the up and down stream undercurrent and the upstream open current infiltrate the well. Construction is simple; investment is economical; and adaptability is wide. All that is needed is a large or small stream with a sandy layer, and the construction may be done in either a new or old watercourse. Moreover, since such a reclining well for temporary use in fighting drought continues to "recline" at the bottom of the stream, it does not impair the movement of flood waters through the watercourse, so it can be a permanent project used in case of drought. SHANGHAI SUBURBS UTILIZE SEED CAKES FOR FODDER

Beijing RENMIN RIBAO in Chinese 8 May 82 p 1

[Article: "Shanghai Suburbs Utilize Cottonseed Cakes and Vegetable Rapeseed Cakes for Fodder"]

[Text] The suburbs of Shanghai Municipality has opened up a new source of protein fodder by taking cottonseed cakes and rapeseed cakes (hereafter shortened to the "two cakes"), which had previously been directly used to fertilize fields, and remaking them into fodder, and then using the dung of domestic animals and fowls to fertilize the fields. This reform has promoted the production of pigs, poultry, eggs, and milk. According to statistics, last year the entire suburban area used about 93.5 million jin of the "two cakes" as fodder, accounting for 42 percent of Shanghai's total output of the "two cakes."

In the past the reason peasants did not use the two cakes for fodder, besides force of habit, was that the cakes contained toxic substances. Now, the "cakes" to be used for fodder are first detoxified and, after being processed into composite fodder, are supplied to the collective fodder grounds and to the commune members.

The utilization of the "two cakes," which are rich in protein, for fodder saves grain, raises the nutritional value of composite fodder, and lowers the cost of raising domestic animals and fowl, thereby improving economic results. In the past 3 years, Silian Commune in Songjiang County has used the "two cakes" to feed pigs, a practice which has greatly raised the level of its pig-raising production. Last year, compared with the period before 1979, when grain was used for fodder, the number of live pigs removed from inventory rose by 34.5 percent, and the average annual surplus in collective pig raising increased by over 48,000 yuan. The poultry farms of Fengxian County utilized the "two cakes" in the scientifically mixed feeding of 4,389 laying hens, and the annual total output of eggs was 117,300 jin, an annual average of 26.7 jin of eggs per chicken with a net income of 5 yuan 4 jiao 1 fen.

Editor's postscript: Cottonseed cakes and rapeseed cakes are top-quality fodder rich in protein, and the country's annual output of the cakes is about 7 billion jin. According to measurements and calculations, if the cakes are used for fodder, their effectiveness in feeding domestic animals and poultry is better than that of the same quantity of grain.

For many years, some localities have not paid attention to opening up this source of fodder and have directly made these cakes into fertilizer. This is a very big waste. Utilization of the cakes as fodder is advantageous for the development of domestic animals and poultry, and the dung of domestic animals and poultry fed with these cakes is a top-quality organic fertilizer. By making this change, the localities will be able to save a large amount of fodder-grain, thus killing several birds with one stone. This course of action by the suburbs of Shanghai Municipality is worth advocating.

PROBLEMS WITH AGRICULTURAL RESPONSIBILITY SYSTEMS AIRED

Tianjin TIANJIN RIBAO in Chinese 7 May 82 p 3

[Article by Wang Longsheng [3769 7893 3932]: "How To Further Perfect Tianjin's Agricultural Production Responsibility System"]

[Text] Following the Third Plenary Session of the 11th Party Central Committee, Tianjin's agricultural production responsibility systems steadily developed, going from a small number of communes and brigades to a large number of communes and brigades, from some operations to all operations in every industry, and from a single form not linked to output to diverse forms mostly linked to output. As of the end of March this year, 16,341 of the 17,635 basic accounting units in the city's 12 suburbs and counties had set up various forms of production responsibility systems. This amounts to 92 percent of the total number of basic accounting units in which responsibility systems linked to output greatly increased in number as compared with last year. To a very large extent they surmounted egalitarianism in the calculation of compensation for work, and effectively aroused the enthusiasm for production of the masses of commune members to promote development of production. Nevertheless, some problems also exist. Principal of these are the following: Some commune brigades apportion the fixing of output quotas for responsibility fields on the basis of the average number of people. This means that households that do not have a large workforce, "cannot eat," while households with a large workforce "cannot get enough to eat." In some communes and brigades the assigned responsibility fields are overly scattered making for difficulties in collective and unified farming. Irrigation water is also not easy for the commune member masses to manage. In some cases the relationship between centralization and the fixing of responsibilities has not been handled well, making it difficult to make the most of the superiority of the collective economy and to arouse the enthusiasm of individual commune members, or even causing damage to collectively own property. In some communes and brigades the relationship among the welfare of the state, of the collective, and of individuals has not been handled correctly. In distributions, individual commune members tend to be favored while insufficient attention is given to collective withholdings for public accumulations. Still some others practice the contracting of jobs to be done within a certain period of time and calculation of compensation on the basis of fixed quotas with no fixing of work quotas or standards for fixing quotas. In actual fact, "during the busy season, jobs are contracted to be done within a specific period of time, and during the slack season a big show of action is made," which is very bad for arousing the enthusiasm for production of the masses of commune members. Further perfection of the city's agricultural production responsibility systems must be done in the spirit of the "Minutes of the National Rural Work Conference" recently forwarded and published by the CCP Central Committee.

1. Among the Various Kinds of Contract Responsibility Systems, First the Contract Distribution of Land Must Be Equitable. Places practicing the fixing of output quotas on an individual household basis and the contracting of work tasks to individual households should encourage proportional contracting for land in accordance with production requirements on the basis of workforces or human labor. Inasmuch as workforce strength and skills differ, the quantity of land contracted may also differ. State staff and employees and cadres should not contract land. In order that land contracted for by commune members will be in one continuous strip, insofar as possible, and not overly scattered, depending on soil quality and different grades, output quota criteria for various parcels of land should be individually evaluated, a mix of good and bad land made, and an average output quota set for the mixture. The collective may keep a small quantity of land in reserve for contracting out to households with large workforces and to redistribute it when population changes occur.

2. Good Solution to the Relationship Between Centralization and Assignment of Responsibilities in Responsibility Systems. In all forms of responsibility systems there are problems in relationships between centralization and assignment of responsibilities. Centralization is for the purpose of making the most of the superiority of the collective economy, while assignment of responsibilities is for the better arousal of the enthusiasm for production of commune members. The objective of both is to promote steady development of production. Ours is a socialist country in which agriculture must keep to the road of socialist collectivization. Consequently the establishment of various forms of responsibility systems must help consolidate and strengthen the collective economy. Any way of doing things that weakens or divides up the collective economy is wrong. Production measures and production projects suited to cooperative production that individual commune member families or households cannot handle by themselves must be centrally managed by collectives, while production measures or projects that commune members can conveniently handle may be contracted to individuals to look after or run. What should be centrally managed and what should be contracted out in any given production brigade should be decided on the basis of realities through the adaptation of general methods to specific situations and specific matters, i.e., on the basis of the levels of development of productivity in the brigade, and on the basis of the management levels of cadres. Whatever should be centralized is then centralized, and whatever should be parceled out is then parceled out. Under most circumstances, essentially there should be "six centralizations," i.e., centralized planting plans, centralized drainage and irrigation, centralized management and use of large machines, centralized organization to eradicate and withstand natural disasters, centralized planning and organization of farmland capital construction, and centralized running of production projects and collective welfare endeavors suited to collective operation. Of the "six centralizations," centralized planning is the nucleus.

Practice has demonstrated that in the raising and use of large livestock animals, a combination of nurture and use is best, and usually three ways of doing this are used. One is care and use centralized in the collective, with systems of personal responsibility established for personnel who care for and use the animals, expenses being paid by the collective or through equal sharing by commune members. Second is collective ownership to preserve capital and value with specialized households caring for the animals, annual withholdings of depreciation expenses being done, the animals being used by a number of households with the households sharing expenses. Positively no "boarding of the animals with different peasant families" is to be allowed. Third is in brigades where livestock animals are fairly scarce and cadre levels are low when brigades are unable to centralize. In such cases, livestock animals are turned over to households at a reasonable price, the funds obtained being deposited in a bank or used to purchase other means of production. When the price set is overly low, it should be corrected inasmuch as this is a disguised way of dividing up collective property. Today, in many communes and brigades where land is scant relative to population, after livestock animals have been turned over to households at a price, the number of livestock animals greatly increases and hay and fodder requirements become very large, while full use cannot be made of the livestock, and thus economic benefits derived are not good. This requires further study for solution.

3. Conscientious Handling of the Relationship Among State, Collective, and Individual Advantages. "Three concurrent concerns" is an important principle in socialist countries, and how well this is done bears on development of national construction, the consolidation and strengthening of the collective economy, and bringing into play the enthusiasm for socialism of individuals. How can it be handled well? On the basis of the experience of some communes and brigades, three problems have to be resolved. First is improvement in the understanding of cadres and of the masses of the relationship between withholdings and accumulations and the consolidation and strengthening of the collective economy, overcoming the mistaken notion among some grassroots level cadres that withholdings and accumulations are useless. On this point, it should be repeatedly explained that centralized administration with the contracting of work tasks to households does not mean the division of fields to be worked alone. Second is solution to the notion among some cadres of "no withholdings from agriculture, but collections from sideline occupations. They must be made to understand that industrial sideline occupations are subject to the effects of industrial readjustment and that earnings are by no means dependable. If there are no withholdings for accumulation from agricultural income, when income from industrial sideline occupations cannot be counted on, and finally at year's end everything is divided up and picked clean, inevitably the collective economy would be weakened. Third is the need to conscientiously figure up two accounts. One is the grain account, i.e., grain purchased by the state, grain to take care of the families of martyrs and military personnel and of the households enjoying the five guarantees [children and infirm old persons who are guaranteed food, clothing, medical care, housing, and burial expenses by the people's communes], grain for use in production etc. The second is the cash account, i.e., the income, expenditure, and accumulation account for collective operations. After this

has been done, the amount of funds to be withheld should be fairly set on the basis of the difference between receipts and expenditures and party distribution policies, and on the basis of comparison of the previous year's gross income and accumulation levels. Last year Yuelong Commune in Ninghe County had an overly low accumulation level, so this year cadres and masses were organized for conscientious figuring of two accounts, and commune accumulations became 2.3 times what they had been in 1981.

4. Formulation of labor quotas to solve egalitarianism in distributions. Statistics show that 6,182, or more than one-third of the more than 16,000 basic accounting units in Tianjin that practice production responsibility systems, have instituted calculation of compensation on the basis of fixed amounts of work to be done in a certain period of time. In an appreciable number of units among them an egalitarian situation continues to exist in the calculation of compensation for labor. In order to overcome this flaw, quota standards for farm work must be set so that most of the farm work assigned can be compensated at a fixed quota. Furthermore inspection of quality of farm work tasks performed should be done to insure quality. If the mass of commune members demand that this form be changed to a responsibility system in which output and calculation of remuneration are linked, all levels of leadership should act on the principle of tailored guidance to give active support and help bring it about.

One important link in the perfection of various responsibility systems is the signing by both sides of contract agreements. The contract agreements should clearly specify the rights and obligations that each side is to assume. Once the agreements have been signed, both sides must carry them out in full and guarantee to honor them. Neither party may take it upon himself to revise or void the agreements. Should disputes arise, they are to be mediated by the next higher echelon or be heard by a judicial department.

Effective work in setting up production team classes and doing a good job of ideological and political work is yet another important assurance for the further perfection of production responsibility systems. In some communes and production teams where production responsibility systems are not run well and problems of various kinds crop up, it is mostly because of weak and lax leadership. Either their own thinking is not straight and they provoke a "confrontation," or they abandon leadership, throw up their hands and do nothing, "letting things take their course." How can responsibility systems be straightened out in this way! Therefore, ideological indoctrination and reorganization of grassroots leadership teams must be carried out to increase the ideological and political consciousness of cadres, and to buttress their dedication to doing a good job of the collective economy and their sense of work responsibility. Additionally, indoctrination of commune members in the "three intense loves," and the "three concurrent concerns" should be done to raise their ideological and political consciousness and their obedience to discipline and respect for the law, so that immediate benefits will be subordinate to long-term benefits, and so that individual benefits will be subordinate to national and collective benefits. Only in this way can agricultural production responsibility systems gradually be perfected.

BROADCAST RALLY URGES ON-TIME PLANTING ACCORDING TO PLAN

Hangzhou ZHEJIANG RIBAO in Chinese 11 May 82 p 1

[Article: "Use Every Available Means To Win Bumper Early Rice Harvest Was Demand of Provincial CCP Committee, and Provincial Government to All Jurisdictions at a Broacast Rally Convened Yesterday. Need for Immediate Survey of How Well Things Have Been Put Into Practice in Early Rice Growing Area, With Sufficient Planting According to Plan Done Wherever Sufficient Planting Has Not Been Done. Unauthorized Changes in Planting of Economic Crops To Be Resolutely Corrected"]

[Text] Yesterday the Zhejiang Provincial CCP Committee and Provincial People's Government convened a broadcast rally for further mobilization of the concerted strength of the broad masses of rural cadres and the masses of commune members throughout the province to do a good job of carefully harvesting and carefully threshing summer-harvested crops and planting a sufficient amount of early rice well, using every available means to win a bumper grain harvest for the year as a whole.

Deputy Provincial Governor Wu Zhiyuan [0702 2784 2268] chaired the broadcast rally. Provincial CCP Committee Secretary and Deputy Provincial Governor Chen Zuolin [7115 0155 7207] spoke at the rally.

The rally analyzed the agricultural production situation. It acknowledged that ever since the lunar new year, all levels of CCP committees and government have diligently carried out the spirit of the "Summary of the Minutes of the National Conference on Rural Work" and of the Provincial CCP Committee Work Conference, and have strengthened leadership of rural work. Thanks to the commune efforts of the broad masses of cadres and commune members plus fairly favorable weather conditions, the agricultural production situation is currently very good. A bumper harvest from summer-harvested crops is in prospect; early rice seedlings are sturdy; quality of early rice transplanting in green manure fields is also not bad; and field care has been taken firmly in hand. The production situation is also rather good for spring tea, spring silkworms, and live hogs. However, in order to fulfill this year's agricultural production quotas, and particularly in order to win a bumper early rice harvest, arduous efforts will still be required. The conference emphatically pointed out that the early rice crop links the past to the future. Not only are yields high, but they are also fairly consistent as well. Early rice output accounts for half the grain output for the year as a whole. Therefore, making sure of the early rice crop is an important key to realizing grain production quotas for the year as a whole. Experiences over the years have shown that once the early rice has been harvested, the initiative has been seized for grain production for the year as a whole. Otherwise, life is hard and a situation of apathy about the year as a whole may form. Right now numerous factors favor a bumper early rice harvest. Now is the important season for tending to green manure field breeding of early rice and making ready to transplant early rice into the fields from which summer crops have been harvested. The opportunity should not be missed; the time will not return. All levels of CCP committees and government must concentrate energies and earnestly strengthen leadership. The broad masses of rural grassroots cadres and commune masses must further act to do a good job of transplanting the early rice and of field care, using every available means to win a bumper early rice harvest.

The rally emphasized the current need to direct attention to the following several tasks:

First, continued attention to planting more early rice so that this year's early rice acreage will exceed last year's. Much work was done and definite achievements scored through implementation of the early rice growing area by all jurisdictions during the previous period, but they are still far short of plan requirements. All jurisdictions should immediately conduct a survey of how well early rice growing was carried out, and where insufficient rice was planted, and planting in accordance with plan should be done. Unauthorized changes in the growing of economic crops should be resolutely corrected. In addition, the masses should be stirred to tap the soil's potential to grow more early rice to the fullest extent possible.

Second is serious attention to the propagation of early rice seedlings. This year many places have sown seedlings very close in the three crop system. Various means should be used to increase seedling quality and prevent jointing of seedlings so they will not be too far along before being transplanted.

Third is keeping apace of the season to assure quality. This year the summer harvested crop area on which rice is being grown has been expanded over last year, but harvest of summer-harvested crops has been delayed, and an increase has occurred in the numbers of spring silkworms incubated. In some places, harvesting, planting, field care, and raising of silkworms have all taken place at the same time, and the conflict in seasons for doing each is fairly pronounced. Overall planning with due consideration to all factors must be done. Arrangements must be made in an overall way, workforces rationally organized, transplanting done on time, and efforts made so that no planting will have to be done in "June fields." In former years the quality of early rice transplanting into fields from which summer-harvested crops had been harvested was somewhat neglected. This year attention should be given this problem. Adequate base fertilizer must be applied, planting done reasonably close, and sufficient basic seedlings transplanted to lay a foundation for high yields from the early rice crop.

Fourth is care immediately following planting, major efforts being devoted to early development. During the past several years, because some places did not give timely care to their early rice crop, it did not develop well in the early stage only to develop wildly in the late stage. Lodging and diseases became serious. This lesson should be learned this year, with care being given even while planting is in progress, with early weeding of the fields and early fertilization to promote early development in an effort to produce high yields from the early rice crop throughout.

The rally also emphasized the need to prepare conscientiously for the late rice crop and autumn production of grains other than rice and wheat, even while devoting attention to early rice crop production. There should be diligent exchange of experiences on late rice crop production, measures for increased yields being put into effects in production teams, households, and fields. Additionally, a good job has to be done in harvesting and threshing carefully the summer harvested crops, experiences in gaining high yields from grains harvested in the spring summarized, and arrangements made about this year's winter season crops.

In conclusion, the rally noted that the key to winning a bumper early rice harvest lies in strengthening leadership and requiring all levels of leaders to further publicize and put into effect the "Summary of the Minutes of the National Conference on Rural Work" approved and sent forward by the CCP Central Committee, and to continue to perfect agricultural production responsibility systems. The job of popularizing and promoting agricultural science and technology should be intensified. There is need for conscientious change in leader workstyles and improvements in leadership methods, with leaders going into the frontline of agriculture to genuinely help the grassroots solve real problems.

ENSURING PLANNED GRAIN AREAS URGED

Hangzhou ZHEJIANG RIBAO in Chinese 15 Mar 82 p 1

[Article by staff commentator: "Ensuring the Planned Area for Food Grains--Second Comment on Exerting Efforts To Grasp This Year's Agriculture"]

[Text] Exerting major efforts to grasp this year's agricultural production and to stabilize the planting area of food grain crops are the urgent tasks at present. Before the busy season of spring tilling, each locality must quickly guarantee the planting area for food grains according to plans.

This year, the task of agricultural production in our province is difficult. To realize a steady increase in the total yield of food grains without a definite planting area will not be possible. Although with good weather conditions and subjective efforts, sometimes the predetermined output can be reached or surpassed even if the sowing area is slightly less, but, we cannot plan for everything and believe that everything will go smoothly. If the area cannot be guaranteed, and if unexpected natural disasters occur, then we will suffer a big loss. Therefore, only by planting the area fully and well according to plan and by exerting efforts in many aspects can we grasp the initiative in food grains production and remain undefeated.

The people depend on food. Exerting efforts to develop food grains production so that the total yield of food grains can steadily increase is an important task of agricultural production. We cannot regard it lightly. But some comrades have had several years of good harvests and have relaxed food grains production. They have expanded the areas for diversification again and again while arranging the distribution of crops, and they have reduced the planting areas of food grains again and again. This incorrect way of thinking and doing things should be highly noticed by the leadership at each level. During the 10 years of internal strife, because of sabotage and destruction by the "gang of four," Zhejiang, known as the home of abundant fish and rice, had to consume "soybeans and sorghum" from the Northeast. This lesson must not be forgotten. Today, we cannot let the people suffer again from a shortage of food grains because we have reduced the area of planting food grains at will. Maybe some comrades would say: "As long as we have money, why should we worry about not being able to purchase food grains?" You are wrong, comrades! If everyone thinks the same way as you and reduces the area of grain fields on a widespread basis, then, no matter how much money you have, where can you go to purchase food grains? The ancestors said: "Pearls, jade, gold and silver cannot be consumed when one is hungry and they cannot be worn as clothes when one is cold." Food grains are the treasures among treasures. We must never sway from the motto of "never relaxing food grains production." We must be firm and unswaying in ensuring the area of grain fields. We do this not because we can reduce or give up the development of economic crops and diversification. Conversely, economic crops must still be actively developed. The problem is that they must not further occupy grain fields. They should develop towards the mountains, hilly areas, rivers, ocean areas and beaches. We should think of ways to increase unit yield.

Aimed at the trend of liberalization in planting at some localities in our province, the party committee and government of each locality should take necessary administrative measures to interfere while strengthening ideological education to guarantee that the planned area of sowing of food grains is assured. Agricultural production is an important part of the nation's planned economy, and it must be guided by state plans. Farmers and production teams can only act within the scope allowed by state plans. The idea that "contracting a piece of land means that the contractor can plant anything" is mistaken. Some commune brigades have realized definite results in educating cadres and commune members and correcting the trend of liberalized planting by confiscating contracted land when the contracting family did not act according to state plans, and planted economic crops or developed diversification in the contracted grain fields. The purpose of such administrative interference is to maintain the whole benefit of the state and at the same time to fundamentally maintain the benefits of the collective and the commune member individual. Of course, we still emphasize ideological education. Administrative interference is only an auxiliary way. We must not believe that we can relax necessary political and ideological work whenever we mention administrative interference or even carry out forced orders and exercise "arbitrary uniformity." As long as we clarify the reason and actively guide the people, we can believe that the broad number of farmers can take the overall situation into consideration and recognize the overall situation and will be willing to accept the guidance of state plans.

Comrades on the agricultural battle front, spring tilling is about to start. We must not wait. Let us quickly stabilize this year's area for planting food grains and concretely implement the plans in every field to establish a good material foundation for the steady increase in food grains production.

YUHANG COUNTY PROJECTS INCREASED RICE PLANTING OVER 1981

Hangzhou ZHEJIANG RIBAO in Chinese 15 Mar 82 p 1

[Article by Zhuo Jiegeng [0587 0094 1649]: "Developing the Potential in Many Aspects To Grasp Food Grains Production Well, Yuhang Will Plant Over 10,000 Mu More of Early Rice Than Last Year"]

[Text] Yuhang County has correctly handled the relationship between state plans and the autonomy of production teams, and between food grain production and diversification. It has developed potential in many ways. The whole county has prepared more than 421,000 mu of early rice, an increase of more than 13,000 mu over last year and an increase of more than 3,000 mu over the area actually planted in 1980.

While arranging this year's agricultural production plan, the county committee and the county government aimed at the problem that some commune brigades have neglected food grain production, organized cadres to conscientiously learn the related documents of the Central Committee, improved everyone's understanding of the importance of developing food grain production so that everyone understood clearly the relationship between correctly handling well food grains production and diversification under the guidance of state plans, and implemented measures to assure the area for early rice. First, they were determined to stop the competition between diversification of food grain crops for planting areas. Some commune brigades revised their planting plans. This year, Anxi Commune originally planned to plant 1,000 mu of wild rice stems, mushrooms and water chestnuts, surpassing the state plans by one and a half times. After learning and discussion, it decided to free the 600 mu beyond the state plans for planting special indigenous crops to plant paddy rice. In developing diversification, many commune brigades actively guided the masses to improve unit yield and to utilize mountain land, miscellaneous land and beaches. In this way, the whole county readjusted and expanded the area of food grains by more than 3,000 mu. Second, they insisted on the triple cropping system to improve the multiple planting index in view of the superior characteristics of natural conditions and the fact that there are more people and less land at the locality. Last year, the whole county planted 10,300 mu of single season hybrids. This year, except for some fields on mountain ridges which receive less sunshine, many commune brigades restored the area of planting early rice. Just this effort alone enabled the whole county to plant 5,400 mu more of early rice than last year. Each commune brigade also paid attention to improving the rate of utilization of seedbeds and appropriately reduced the seedbeds specifically utilized for late rice. This effort is expected to provide nearly 1,000 mu more for planting early rice. In addition, each county farm has also developed the potential of the land fully, so that the area of planting early rice can be enlarged by more than 3,000 mu.

To produce food grains well, to complete this year's agricultural production tasks and to complete them with surplus, recently, the cadres at each level throughout the county went deeply into the frontlines of spring tilling, and they inspected the planting plans for various crops and measures to increase yield so that every aspect is implemented. Sandun Prefecture combined efforts with signing contracts for work to implement plans for food grains production and planting, the distribution of varieties, the output goals and the state's procurement and surplus procurement tasks together for the production teams and the contract work groups to carry out. Of the 641 production teams throughout the prefecture implementing contracting production to the group and linking production with remuneration, 74 teams have already signed such contracts.

THREE TECHNIQUES TO INCREASE EARLY RICE OUTPUT GIVEN

Hangzhou ZHEJIANG RIBAO in Chinese 15 Mar 82 p 1

[Article by Xie Renxing [6200 0088 5281] of the Shaoxing Prefecture Agricultural Science Institute: "Strive To Plant More and Produce High Yields of Early Rice by the Three Techniques"]

[Text] Early rice is our province's high yielding and stable yielding single season crop. What technical measures can be taken to strive for planting more and producing high yields of early rice? We believe:

I. Late rice must be cultivated in two stages as much as possible. This can reduce the area of special seedbeds and provide more land for planting early rice. This will establish a good foundation for cultivating sufficient and good and strong seedlings of late rice. For example, if we arrange 10 percent of the land for planting early maturing varieties of early rice as seedling plots for late rice, then, 90 percent of the area of early rice can be used for early rice and the area of seedling plots for late rice can be enlarged to 20 percent.

II. The unit yield of early and intermediate maturing early rice can be improved. There are four ways: 1) Early and intermediate maturing varieties can be matched with early maturing barley fields, guang lu ai No 4 and such late maturing varieties can be matched with green manure fields, thus, "shifting of varieties" can be carried out and this can prevent damage to panicle bearing and heading of early and intermediate maturing varieties by low temperatures. 2) Strong seedlings of appropriate age can be cultivated. The suitable seedling age of early maturing varieties is within 25 days, and that of intermediate maturing varieties is within 30 days. The amount of sowing in the seedling plots is 120 jin to 140 jin. The main field uses about 20 jin of seeds. 3) Fertilizers in appropriate amounts should be applied early. Base manure and seedling fertilizers constitute two-thirds the total amount of fertilizers, and fertilizers for panicle growth constitute one-third. 4) Management should be early and the fields should be lightly dried. The field should be weeded 5 days after planting and water should be drained to dry the fields lightly. The per mu yield of early maturing er jiu qing planted in the high yielding experimental field of the Shaoxing Prefecture Agricultural Science Institute reached 940 jin.

III. The unit yield of "late triple cropping" early rice should be improved. 1) We should continue to popularize sparse sowing to cultivate strong seedlings and prevent overaging or underaging. Generally, the amount of sowing in seedling plots is 60 to 80 jin. One mu of seedbed can supply plants for 5 to 6 mu in the large fields. 2) We should expand two-stage cultivation of seedlings and the method of removing some seedlings and leaving some seedlings for cultivation, i.e., during the first stage, 250 to 300 jin of seeds can be sown per mu for dry cultivation to a seedling age of about 15 days. During the second stage, green manure fields can be used as temporary beds. The seedlings should be densely planted in the temporary beds with soil attached at 2 cun times 2 cun. Each bunch should have 2 to 3 plants. When transplating, one plant is left and the rest are transplanted. The removed seedlings are planted in fields of late maturing winter crops, and the remaining seedlings will serve as seedbed seedlings. This method can produce high yields of late triple cropping early rice and provide fertilizers for early rice in the seedbeds, and it can increase the yield of food grains.

NEW EARLY RICE PLANTING TECHNIQUES DISCUSSED

Hangzhou ZHEJIANG RIBAO in Chinese 15 Mar 82 p 1

[Article by Zhang Yueqiang [1728 6390 1730] of the Changkou Supply and Marketing Cooperative in Fuyang County: "Food Grains Can Be Increased Without Spending More, We Only Have To Change the 'Square' Into 'Length' and 'North and South' Into 'East and West'"]

[Text] In recent years, some regions in our province have conducted a planting experiment to plant "wide rows and narrow plants" and "from east to west." Both of these methods realized welcomed results of increased yields. Jinhua Prefecture changed the original 5 x 5 (cun) or 5 x 4 (cun) square planting to 7 x 2.5 (cun) or 6 x 2.5 (cun) wide row and narrow plants. The average per mu yield of early rice reached 800 to 900 jin with the highest reaching more than 1,100 jin. Under the same measures of cultivation, the new arrangement produced an increased yield of 5 to 8 percent over square planting. They also conducted planting experiments in different directions using three different types of arrangements in dense planting. As a result, the average per mu yield of early rice in the "east and west rows" was 860 jin, an increase of 8.4 percent over the south and north rows.

The reason that "wide rows and narrow plants" and "east and west rows" produced increased yields was mainly due to an increase in aeration and light penetration. The leaf area increased more quickly, the microclimate in the field improved, the rate of utilization of light energy was increased, and the original "superiority of the side rows" of plants was more fully developed and utilized. According to foreign experiments, after wheat was planted in "east and west rows," it could produce over 20 jin more per mu than wheat planted in south and north rows. They believed this was due to the function of the earth's magnetic field. Experiments showed that root and bud of corn and wheat seeds will turn towards the south pole after being placed towards the north pole for a period. This is called geomagnetic polarization of the root system. Therefore, the root systems of most crops focus towards the south and extend towards the south. After crops are planted in east and west rows, their root system can extend, they can root and spread towards the south in the soil and become perpendicular to the planting rows. This increases the rate of utilization of the area of the soil compared to that of plants planted in north and south rows. The nutrients and moisture in the soil are fully utilized by the crops and the yield increases.

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 2, 1982 pp 6-10

TEXT OF ENGLISH ABSTRACT: This paper presents the results of radiation-breeding of restorer lines in hybrid rice. The radiosensitivity of "Taiyin No 1" at various stages of development, the mutation frequency resulting from ^{60}Co γ-ray irradiation, and the inheritance and segregation of some characteristics of the early mutants have been studied. The restoring ability of early strains has also received preliminary study.

The experimental results indicate that γ-ray irradiation is an effective way of improving restorer lines in hybrid rice.

TITLE: "Primary Study on the Control of Corn Borer by Pine Moth Trichogramma Labeled with ^{32}P"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 2, 1982 pp 31-36

TEXT OF ENGLISH ABSTRACT: The pine moth Trichogramma has been used to control the injurious insects in agriculture and forestry in China. The Trichogramma were released in an area of about 10 million mu. Good results were obtained. Now the pine moth Trichogramma is being used in the suburbs of Beijing. In the past 3 years it has been released in an area of about 1 million mu every year. The parasitic rate of the ovum of the corn borer was 70-80 percent.

[Continuation of YUANZINENG NONGYE YINGYONG No 2, 1982 pp 31-36]

In order to study the ability to scout for the host, the parasitic effect on the host and the competitive ability of the pine moth Trichogramma with the corn borer Trichogramma in the field, a syrup with ^{32}P 25μ Ci/ml was prepared to label the pine moth Trichogramma by feeding it directly. This treatment was not harmful to the insects. It was easy to discover the parasitic egg lump of the corn borer carrying radioactivity which could be measured with nuclear instruments and autoradiography. It has been proved that the pine moth Trichogramma in the field has a stronger ability of scouting for the host and a higher parasitic effect.

TITLE: "Problems of Soil and Water in the Basic Construction of Farming Fields"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 5, 23 May 82 pp 3-9

ABSTRACT: The basic construction of fields is a task involving utilizing as well as reforming nature. It is also the foundation of agricultural modernization. Its major aim is to realize comprehensive treatment of the mountain, the water, the field, the forest, and the road so as to construct fields of high and stable yield, to develop multiple operations, and to promote agricultural production. Through a lengthy discussion of the meaning of ecological systems and the relationship between basic construction of farm land and the ecological system of the farm land, the paper proceeds to explain that water and soil resources form the major considerations of such basic construction project With regard to water, attention must be given to the interrelationship among the atmospheric water, the surface water, the soil water, and the ground water to treat the four as a unified entity for unified adjustment and arrangement. This is especially important in case of saline, alkaline lands and paddies. Regarding soil, the land should be made level, the layer of topsoil should be made thicker, organic fertilizer should be added, irrigation and drainage systems should be made convenient to operate, and a cropping system should be adopted to combine land utilization with land nurturing.

TITLE: "A Tentative Discussion on the Shift of Focalpoint of Basic Construction in the Paddy Rice Regions of the South"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 5, 23 May 82 pp 10-15

ABSTRACT: In the paddy rice regions of the South, after the problem of irrigation is basically resolved, the next major aim of farm land basic construction becomes the chief concern in the development of agriculture. For example, in the subtropical Yichun Prefecture, the condition of irrigation was poor in the 50's and farming depended upon rainfall in most of the areas while the harvest of the dry acreage was less than 1/4 of that of paddies. In the 70's, there are many irrigation stations and it is in a year of above normal rainfall when the yield of early rice crop suffers. The major concern has now been shifted to flood control to reconstruct waterlogged paddies by lowering the water table in order to obtain the optimal economic benefit from farm land basic construction investment. The goal of combining the engineering network of 20,000 reservoirs in these regions with 6,800 small hydroelectric power stations, a drainage system to coordinate with the existing irrigation facilities, and a cropping system of rice-rice-green manure is described as the focal point of current attention.

TITLE: "A Survey of the Economic Condition of the 10,000 Households in Anhui Province"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 5, 23 May 82 pp 16-20

ABSTRACT: For the purpose of mastering the actual condition of economic development in the rural villages of Anhui Province, the department spent close to 2 months last year to carry out a large scale survey of the 10,543 households of the 69 counties of the province. The survey includes the following items: (1) Production development: In 1981, the per capita grain production is found to be 1,153.19 jin, an increase of 30.62 percent; oil 67.64 jin, an increase of 76.65 percent; cotton 9.11 jin, an increase of 32.41 percent,with 0.96 pigs per household, an increase of 4.35 percent. (2) Net increase of income: In 1981, the per capita income is 364.22 yuan, an increase of 39.03 percent over that of 1980. After deductions of tax to the State, production costs, etc. the average net income of a commune member is 273.87 yuan, an increase of 46.2 percent. (3) Increased contribution: The sale to the State of grain is 258.87 jin per capita, an increase of 49.45 percent; oil 45.12 jin, an increase of 101.07 percent; cotton 8.14 jin, an increase of 36.58 percent, and 0.65 pigs per household, an increase of 1.56 percent. (4) Increased value of fixed assets: The

[continuation of NONGYE JINGJI WENTI No 5, 1982 pp 16-20]

value of fixed assets, including agricultural machinery, draft animals, large farm implements, and warehouses is 394.3 yuan per household, an increase of 43 percent, and 67.64 per capita, an increase of 41.48 percent. (5) Improved standard of living of farmers: In 1981, the grain consumption is 701.8 jin per capita, edible vegetable and animal oil 8.86 jin, an increase of 19.41 percent, meat, fish, poultry, and eggs 22.05 jin, an increase of 28.12 percent, sugar 2.85 jin, an increase of 21.28 percent, cloth 19.4 chi, an increase of 12.33 percent, housing 4.78 rooms, an increase of 14.08 percent, bicycle 0.23 per household,an increase of 35.29 percent, sewing machine 0.19 per household, an increase of 35.71 percent, radio 0.48 per household, an increase of 29.73 percent, watch 0.45 per household, an increase of 36.36 percent, savings 34.87 yuan per capita, an increase of 81.9 percent. Judging from the crop acreage, the grain acreage was 124 thousand mu in 1980 and 140,000 mu in 1981; the economic [cash] crop acreage was 22,150 mu in 1980 and 30,908 mu in 1981, amounting to increases of 12.9 and 39.5 percent respectively. Judging from the rate of development, the grain production was 467.9 million jin in 1980 and 634.6 million jin in 1981, an increase of 35.6 percent. The total income was 745.1 million yuan in 1980 and 1070 million yuan in 1981, an increase of 44.2 percent. The income from economic crops was 216.5 million yuan in 1980 and 373.1 million yuan in 1981, an increase of 72.3 percent. Condition of growth in family auxiliary industries is also reported.

TITLE: "Analysis of the New Economic Combination System of Rural Villages"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 5, 23 May 82 pp 21-25

ABSTRACT: Following the implementation of the system of agricultural production responsibilities, a new type of socialist economic organizations has emerged. They are economic combination systems [associations] of various shapes and forms, including household with household, household with brigade, with some crossing over commune and prefecture barriers. As the great change occurred to rural economy in 1979, within the collectives, the error of egalitarianism is corrected and the production relationship adjusted to reinforce the autonomy of the collective as well as its members. The crop arrangement has been adjusted to develop multiple production. Rural auxiliary industries and market trading have been encouraged to result in the appearance of prosperity. Of the many forms of economic associations, the 3 major ones are: (1) Production associations to resolve problems of production materials, capital shortages, etc.; (2) Technological associations to engage in construction, paper-making, forestation etc. (3) Labor associations for transportation, processing agricultural by-products, etc.

TITLE: "Fresh Water Fish-farming Should be Widely Developed in Hubei"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 5, 23 May 82 pp 47-51

ABSTRACT: Hubei has 1/10 of the nation's fresh water area capable of being used for fish culture. According to a 1980 statistical report, it has 13.33 million mu of water surface, of which 5.85 million mu are rivers. The remaining may all be used to raise fish to make the area the second largest in the nation, second only to Anhui. Since the liberation, fish production increased steadily for 10 years before it began to decline in 1960 as a result of the one-sided emphasis on grain production. The importance of fish culture was again brought to the attention of the leaders in 1980 and the production grew once again. Of the existing 7.48 million mu of fresh water surface, 4.13 million mu are being utilized at present, amounting to 55.2 percent. Compared with 1949, the water surface has been shrinking at an average rate of 290,000 mu a year, resulting from lakeshore encroachment to create new cropland. The constant discharge of large quantities of industrial waste far exceeding the self-cleansing capacity of the waters is another problem. Moreover, fish culture has also suffered from leftist policy errors and the frequent alterations of the system of administrating the province's fish production have caused the ratio of the value of marine products in the agricultural economy to drop year after year.

TITLE: "[State-operated] Farms Should Handle Their Relationship With Commune-Brigades Well to March Forward Together"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 4, 24 Apr 82 pp 4-6

ABSTRACT: In the course of socialist construction, although the various sectors or departments do have common goals and identical interests, there may still be this and that contradiction in their interrelationship arising from their viewing a problem from different angles. This sort of contradiction belongs to the type of internal contradictions of the people and generally speaking they may be resolved through the method of solidarity-criticism-solidarity. Chairman Mao wrote specially on the subject and proposed theories and methods. We must continue to follow these proposals. The relationship between a State-operated farm and communes or brigades is a relationship among brothers. When they are neighbors seeing one another daily, problems are difficult to avoid. Such problems currently include 2 types: (1) Masses of a few commune-brigades go to a farm like a mob to take grain, rubber, and other crops; (2) Contradictions arising from day to day work. The first type is a crime against the law and should be punished as such. The second type should be resolved among themselves through mutual concern and negotiations.

[continuation of ZHONGGUO NONGKEN No 4, 1982 pp 4-6]

The distinction between the 2 types of problems does not appear to be clear-cut, if an incident told in the paper is any indication. The Xinguang Farm of Guangxi, a fruit-growing farm, experienced a tense relationship with a neighboring commune. The paper does not mention details of the dispute. In 1978, members of the commune decided to resolve the dispute by themselves. They cut down 3,000 mu of lemon trees, more than 1000 mu of bamboos, and stole the oranges. The farm brought the case to the court but before the court had time to hear one such case another had occurred. The leaders of the commune would not see those of the farm at first until finally the farm invited members of the commune to attend two meetings a year to discuss problems of mutual interest. A deputy-director of the farm was assigned the special job of visiting the commune to help the commune resolve its production and other problems. The problem between the farm and the commune was thus resolved and they felt very good about one another since then.

TITLE: "Full and Effective Use of Agricultural Equipment Loans"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 4, 24 Apr 82 pp 8-9

ABSTRACT: At present, there are 3 major sources of capital for projects of agricultural and land reclamation construction: State approppariation, industrial surplus funds, and bank loans. The State has financial difficulties now and will be unable to increase agricultural investment for years to come. It appears that if the agricultural and land rclamation economy is to continue its steady development, it should find all sorts of ways to increase the capital accumulation within the industry on the one hand; on the other hand bank loans should be fully and effectively utilized. Some comrades have doubts about borrowing, however. They say that money for production construction should naturally come from the State. If the State gives the money we go ahead with the project; if there is no money there is no project. The paper argues that since the adoption of flexible economic policies, bank deposits have been growing very fast. In 1980, bank deposits amounted to 28.3 percent of the year's national income. From 1980 to 1982, short-term loans borrowed by State-operated farms for equipment from the agricultural banks came close to 6 hundred million yuan. Full and effective use of bank loans for agricultural development is urged by the author.

TITLE: "Economic Association Promoted to Develop the Food Industry"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 4, 24 Apr 82 pp 13-14

ABSTRACT: In the 3 years since the establishment of the Changjiang Agricultural, Industrial, and Commercial Joint Company of Chongqing City, there have been new breakthroughs on the original foundation of the food industry. The value of products in 1980 was 13.23 million yuan and the profit was 2.06 million yuan. In 1981, the value of products was 20 million yuan, an increase of 51 percent; the profit was 3 million yuan, an increase of 46 percent. The major content of the joint company is to process and sell the agricultural and animal husbandry products produced by itself. It has established15 food processing plants and machine shops emphasizing dairy products, canned goods, soft drinks, and tea. The food industry has in turn spurred the establishment of industries of paper boxes, paper bottle caps, plastic bottles, plastic bags, packaging paper, printed products, etc. The joint company owns, first of all, mountain lands, forests, fresh water areas, etc. Additionally, it forms economic associations with communes and brigades. Its raw material supplies are; therefore, plentiful and the cost is low. It needs very little capital for machinery for very fast returns. The quality of its products is good and the price is low; therefore it can withstand competition very well.

ORG: Bureau of Planning, Ministry of Agriculture and Land Reclamation

TITLE: "General Condition of Agricultural and Reclamation Production Construction in China in 1981"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 5, 24 May 82 pp 3-5

ABSTRACT: In 1981, the entire agricultural and reclamation system of China earnestly implemented the central party's policy of continued economic readjustment to promote the economic responsibility system. All over the country, aside from a yield reduction of grain and beans due to natural calamities, there were general yield increases of economic crops to produce agricultural-industrial products valued at 8.6 billion yuan, of which the value of agricultural products was 4.4 billion yuan and that of industrial products 4.2 billion yuan (based on the price level of 1970). A profit of 200+ million yuan was obtained. Among the agricultural products, the value of products of the farming system was 2.5 billion yuan, amounting to 56.2 percent; that of the forestry system 890 million yuan, amounting to 20 percent (in which 760 million yuan were from the rubber industry); the animal husbandry industry 610 million yuan, amounting to 13.9 percent; the auxiliary industry 420 million yuan, amounting to 9.5 percent; the fishery industry 20 million yuan, amounting to 0.4 percent. The acreage of grains and beans was 52.19 million mu and the products totaled 1,217,000 jin; the acreage was 2.7 percent less than that of the previous year and the total production reduction was 20 percent. The cotton acreage was 28.15 million mu

[continuation of ZHONGGUO NONGKEN No 5, 1982 pp 3-5]

and the total production was 2.22 million dan; the acreage was enlarged 14.7 percent and the production increased 25.4 percent. The acreage of oils was 3.73 million mu and the total production was 3,156,000 million dan. The acreage was enlarged 10.7 percent; the production increased 28.5 percent. The acreage of sugar was 1,058,000 mu and the production was 36.08 million dan. The acreage was enlarged 6 percent and the production increased 23.5 percent. The total sale of the agricultural and reclamation system in 1981 was 4.45 billion yuan, an increase of 5.5 percent over the previous year. The sale of grains and beans was 4.21 billion jin, a reduction of 31.2 percent. The sale of commercial grains and beans amounted to 34.5 percent, a reduction of 5.4 percent (in which 370 million jin were soybean). The sale of cotton was 1,983,000 jin; that of oils 2.32 million jin; that of meats 305 million jin amounting to an increase of 11.3 percent (in which the sale of commercial meats was 58 percent, same as that of the previous year). The exported products of the agricultural and reclamation system amounted to 506 million yuan, an increase of 10.9 percent over those of the previous year. The major exported products included 150,000 tons of soybean, 4,000 tons of rice, 308,000 pigs, and 14,000 head of cattle.

TITLE: "Why Can the Guizhou Agricultural and Land Reclamation Enterprise Raise Its Economic Benefits in a Year of Great Natural Disaster?"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 5, 24 May 82 pp 15-16

ABSTRACT: In 1981, Guizhou Province suffered the severest drought in 60 years, but the 42 State-operated farms of the agricultural and land reclamation system reaped the greatest harvest in the 29 years since it was first established. Compared with 1980, the farms produced 25,000 dan tea leaves , an increase of 17.8 percent, 910 million jin of milk, an increase of 3.41 percent, 6,500 dan of oil materials, an increase of 66.79 percent, 780 thousand jin of pork, an increase of 2.63 percent. The total income was 21 million yuan, an increase of 20.3 percent over that of 1980. The paper credits the following for the great success in the midst of adversity: (1)Realistically, adjusting the crop structure to take advantage of the natural condition of mountainous regions; (2)Eliminating the errors of egalitarianism and implementing various forms of production responsibility system; (3) Carrying out joint operation of agriculture, industry, and commerce to change the condition of producing raw materials only.

ORG: The 850 Farm, Heilongjiang Province

TITLE: "Grain-Fertilizer Rotated Cropping System in the Eastern Part of Heilongjiang Province"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 5, 24 May 82 pp 19-20

ABSTRACT: Since the reclamation of the eastern part of Heilongjiang, an imbalance between land utilization and land nurturing has become a general problem due to insufficient supplement of organic matter. Beginning in 1963, an experiment has been carried out to study ways of rotating grain and green mature. After the wheat harvest, a crop of fast growing green manure is cultivated and turned over during the same year. The current system includes a 3 to 4 section rotation of corn, sorghum, millet, paddy rice, etc - soybean - wheat, being one crop a year planted in the spring and harvested in autumn. The growth and development period of wheat is short, however to leave 1.5-2 months of growing season before the first frost. This is enough time for a crop of rape or pea to produce 1,000 - 3,000 jin/mu of green manure, which are capable of growing until 16 Oct, one to two weeks after the first frost. The green manure crop should be turned over late Sep to early Oct, but if the soil moisture is good, it may be left to grow until the middle of Oct. In 1980, this system had been extended to 300,000 mu in the farm.

TITLE: "Agronomical Expressions of Shuanggui No 1 and Its High Yield Cultivation Technique"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 3, 8 May 82 pp 1-4

ABSTRACT: Shuanggui No 1, same as Shuanggui-210, is a new paddy rice breed, bred out by Guangdong Provincial Academy of Agricultural Sciences' Research Institute of Rice through hybridization of Guiyangai C17 x Guichao No 2. For the purpose of clarifying its agronomical expressions and cultivation technique, the bureau carried out field tests, in cooperation with Fanyu County Institute of Agricultural Sciences, Conghua County Institute of Agricultural Sciences, Hua County Donggong Commune Agricultural Science Station, and Fanyu County Shidong Brigade Agricultural Science Station. Judging from observations of large acreages in a number of counties, communes, and brigades, the paper summarizes that as the early crop, the growth and development period is 140-165 days, i.e. 99-107 days after transplantation, as the late crop in the autumn, it is 112-126 days, i.e. 92-103 days after transplantation. Its spike development process, stem and leaf morphology, spike

[continuation of GUANGDONG NONGYE KEXUE No 3, 1982 pp 1-4]

and grain structure, and disease resistance are reported according to the survey data. The second half of the paper is devoted to discussions of its high yield cultivation technique, including the proper seeding time, suitably early transplanting, reasonable density of no more than 3-5 seedlings per hole, the principle of fertilizer application, and arrangements for its utilization as either the early or the late rice crop.

AUTHOR: LUO Jinling [5012 6855 6845]

ORG: Guangdong Provincial Weather Station

TITLE: "Classification of Annual Rainfall of the First High Water Stage and Its Relationship With Early Rice Production"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 3, 8 May 82 pp 11-13

ABSTRACT: Based upon the rainfall data of 1959-1980 of the station, the paper proceeds to explain that whether a particular place is suffering from flood calamity in a given month is determined by the total rainfall of that month in that place as well as the degree of concentration of rainfall in that month. When the former is represented by $\frac{\Delta R}{R}$ and latter by $\frac{\Delta r}{r} + 1$, the sum of the two represents the floodwater index of that month in that place. When the floodwater indices of Apr, May, and Jun of that year in that place are added together, the annual floodwater index for that year's first high water stage for that place is obtained. The annual floodwater index demonstrates the amount of rainfall, the condition of concentration, and the size of the affected area. The greater is the index the more serious is the condition of the rain. When the hours of sunlight is represented by $\frac{\Delta S}{S}$, $(\frac{\Delta R_2}{R_2} - \frac{\Delta S}{S})$ represents the year's index for the early rice crop. As 70 percent of the yield of the early rice crop is formed after the heading-blooming stage, the yield and the index have a definite relationship. When the index is < 8, the possibility of yield increase is 73 percent; if it is > 8, the possibility of yield reduction is 71 percent.

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 3, 8 May 82 pp 31-34

ABSTRACT: Rice ragged stunt was first reported in the Philippines in 1977. In China, it was first discovered in Fujian and Guangdong Provinces in 1978-79 and it was also reported in Jiangxi in 1980. According to surveys of affected fields, it is generally a scattered incidence but in serious cases, 90 percent of the rice plants may be diseased to cause a total loss of harvest for the paddy. The incidence, the symptom, the electromicroscopic observation, the disease-spreading characteristic of brown planthopper (Nilaparvata lugens (Stål), the determination of disease resistance of major breeds, and the interrelationship between the virus and the vector are reported, on the basis of the survey data of Jul-Sep, 80 of various locations in Guangdong Province.

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 6, 1982 pp 8-15

TEXT OF ENGLISH ABSTRACT: Samples of hybrid rice and its three lines obtained from Jianhu County, Jiangsu Province, and from several southern provinces were subjected to random sampling test and assessment of off-types during 1977-81. The pollen fertility of male sterile lines from different districts was checked, the combining ability of male sterile lines and restorers was estimated and the yield of hybrid rice from various districts and the productivities of single plants with different mixture ratios were compared. The experimental results showed that the deterioration of hybrid rice was mainly due to the mechanical mixture and biological contamination. No so-called degeneration of hybrid rice and its three lines could be found after factors conducive to mixture were eliminated. Thus, preventing mechanical mixture and biological contamination should be a critical measure for the rejuvenation of the hybrid rice.

TITLE: "Progress of Resistance Breeding to Fusarium Wilt and Verticilium Wilt of Cotton in China"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 6, 1982 pp 16-22

TEXT OF ENGLISH ABSTRACT: Fusarium and Verticillium wilts detrimental to yield increase have become a great menace in the cotton growing areas in China. The area of infected cotton fields amounts to 19.4 percent. It is proven in practice in China and in other countries that adoption of disease-resistant varieties is the most beneficial measure. In the 31 years since the founding of the PRC, 47 varieties (or lines) in various types have been developed. The Fusarium resistant varieties undergoing the regional variety test for disease resistance and recommended for planting on a large scale are Shaanmian 401, 86-1, Shaanmian 4, Shaanmian 6, 5245 and Chuan 73-27. The Verticillium wilt resistant varieties recommended are Liaomian 5 and Zhongmian 9. The Fusarium and Verticillium wilt resistant variety released is Shaan 1155. The area under disease-resistant cotton in the whole country totals up to 6 million mu. Wilt in the seriously infected

[Continuation of ZHONGGUO NONGYE KEXUE No 6, 1982 pp 16-22]

areas has been controlled, and cotton production is swinging a new direction. As a consequence, the loss of 1.5 million piculs of lint cotton every year is avoided.

Trials show that the Fusarium wilt resistant varieties developed in our country have strong resistance and a high consistency in yield are are widely adapted. The resistance of the Verticillium wilt resistant varieties approximates that of the varieties used in other countries. Their productivity and lint quality improve yearly. The discrepancy between them and the conventional productive susceptible varieties of good qualities becomes less as time progresses. Rich experience is gained step by step, advances are made in the theory of cotton breeding, the ranks of cotton breeders are enlarged and constant improvement is made in the methods of cotton breeding. All these present a bright future for the third generation of disease resistant varieties which are marked for their resistance to both wilts and the acceptable combination of productivity and good lint quality.

TITLE: "Preliminary Study on the Evaluation of Economic Results in Agricultural Scientific Research"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 6, 1982 pp 89-94

TEXT OF ENGLISH ABSTRACT: The authors hold that the contribution of agricultural scientific research to the growth of the national economy is measured according to the benefits it offers to the development of agriculture.

The economic results of agricultural scientific research should be evaluated from the point of view of their optimum service to socioeconomic development. They reflect the proportionate relationship between labor consumed and effective output as well as the incremental relationship between the economic results of the new research and those of the previous ones.

The authors propose an economic critical boundary for extension and the use of the research achievement indicators of the economic effects and methods of calculation.

[Continuation of ZHONGGUO NONGYE KEXUE No 6, 1982 pp 89-94]

They suggest that: The increase of social gross production of agricultural products, the net income increment, the research returns as well as the functional share of agricultural sciences and techniques should all be considered in the total increment of agricultural productivity and in its growth rate. The direct economic results of a new variety of cotton, "Lu-Mian No 1," are estimated.

TITLE: "The Technological Characteristic of Weather Station Forecasting and Its Reform and Improvement"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 3, 10 Mar 82 pp 35-36

ABSTRACT: The characteristic of the forecasting technique of China's county weather stations is to combine weather chart, the data of the continuously evolving meteorological factors, and the weather forecasting experience accumulated by local weather forecasters and masses. The author affirms the correctness of this technique and believes that if it is seriously carried out the level of forecasting by the county weather stations may be improved. The author also suggests that in order to improve the forecasting technique of the county stations, it is necessary to develop radiophotography, cloud observation, comprehensive analysis, historical probability, personnel training, and a balance between new and old techniques in every county weather station.

I. GENERAL INFORMATION

BRIEFS

NORTHERN CHINA RICE--North China has begun to plant a new hybrid rice which yields 750 to 1,100 kilogrammes more a hectare than other varieties, according to agronomist Yang Zhenyu, who developed the new strain. More than 66,000 hectares of farmland have been planted with the hybrid rice "Liyou 57." The new variety is the first Geng type hybrid rice adapted to the weather of northern China. Geng type rice has a longer growing season and is more glutinous than Xian type which is grown in southern China. In Dawa County, Liaoning Province, where 16,000 hectares of farmland were planted with "Liyou 57" the output averaged 8,250 kilogrammes a hectare last year. On small experimental plots, the yield was as high as 12,000 kilogrammes a hectare. [Excerpt] [Beijing CHINA DAILY in English 3 Aug 82 p 3]

PRC PRODUCTION BRIGADES--The number of production brigades who have prospered this year has nearly doubled. 10,943 brigades fall into this category, up from 5,569 last year. These brigades have an average annual per capita income of 300 yuan. This means 900 yuan yearly for a family of three. They comprise 1.52 percent of the total number of brigades in the country and are mostly located in Shanghai, Beijing and Guangdong Province. Beijing inner Mongolia autonomous region, Jilin, Jiangsu, Guangdong and Anhui had the highest number of brigades who prospered. [Text] [Beijing CHINA DAILY in English 3 Aug 82 p 3]

SUGAR PRODUCTION--Beijing, 25 Jun (XINHUA)--China produced 3.4 million tons of sugar in the 1981-1982 refining season which has just ended, according to the Ministry of Light Industry. This is 13.3 percent up on the previous refining season which was a record itself. Sugar output has registered an 89 percent increase since 1977. Cane sugar production went up 16.1 percent this year with an output of 2.74 million tons while beet sugar increased 3 percent. Support to peasants growing sugar cane in the form of higher purchasing prices and provision of grain were the main reasons for the increase. Chinese made presses capable of refining 400,000 tons of sugar were installed this year, mainly in existing refineries. [Text] [Beijing XINHUA in English 1214 GMT 25 Jun 82 OW]

SURPLUS GRAIN STOCKS POSE PROBLEM FOR CHUXIAN PREFECTURE

Beijing RENMIN RIBAO in Chinese 13 May 82 p 1

[Reporters' letter: "Solve as Fast as Possible Chuxian Prefecture's Problem of Transferring Grain and Rape to Other Localities"]

[Text] In the middle and latter parts of Arpil, just in the season when rape was blossoming and wheat was earing, we reporters paid a visit to Dingyuan, Fengyang, and Jiashan counties in Chuxian Prefecture. Wherever we went, the cadres and masses in succession reported that "it is hard to sell grain," and many times we saw masses in long lines at grain supply centers. Because some granaries were already full to the brim, there was no choice but to build open-air depots; because in some places there was no space to pile up grain, there was no choice but to stop purchasing grain.

Over the past 2 years, Chuxian Prefecture has changed its longstanding passive situation of "depending for food on grain resold by the state to the place of production." On the foundation of the peasants' standard of living rising year after year, the amount of grain and rape sold to the state has increased year after year. According to statistics compiled by the prefecture's grain burea, by 20 April more than 1.2 billion jin of grain had been put into storage throughout the prefecture, an increase of close to 1.5 times above the prefecture's grain state-purchase and state-excess purchase quotas and an increase of over 500 million jin in the total amount of grain in storage as compared with that of the previous year period; over 200 million jin of oil-bearing crops are already in storage, over 7 times above the state purchase quotas and over 100 million jin above that of the previous year period. For the period from January through March of this year, the amount of grain in storage throughout the prefecture was over 110 million jin, over 3 times above that of the corresponding period of last year. After the beginning of April, the daily amount being put in storage was still 1 million to 1.5 million jin.

Why, in this time of temporary shortage, has there appeared in Chuxian Prefecture a situation in which too much grain has been sold. According to our understanding, this is mainly for the following two reasons: The first reason is that last year the scale of the growth in output of grain and rape was large and the masses have a lot of grain in hand. At present, the grain stored up in commune member homes is generally enough for the families to eat until autumn grain comes in this year, and many families would not be able to finish eating the stored grain until next year's summer harvest. The other reason is that a lot of summer-ripening crops were planted and are growing well; the preliminary estimate is that there will be about a 20 percent increase in output over that of last year. Seeing the large batch of new grain that will come into their hands, the peasants one after another demand even more to sell the surplus grain.

Currently, the outstanding problem existing in grain supply centers in Chuxian Prefecture is: their storage capacity is inadequate and the transfer of grain and rape to other localities is not done in a timely fashion, and this seriously affects purchasing work. According to statistics, last year the prefecture's 170 grain supply centers set up a total of 1,528 open-air depots, and there are now over 100 million jin of grain in open-air depots. Therefore, the local leaders at every level and the comrades engaged in grain work urgently hope that the departments concerned will quickly transfer the existing grain stocks to other localities, in order to solve the current problem of the masses' "grain-selling difficulty" and to make good preparations for purchases of summer grain and rape.

BRIEFS

LIXIN COUNTY WHEAT HARVEST--Anhui's Lixin County has reaped a bumper harvest from its 1.116 million mu of wheat this year, with its per-mu yield reaching as high as 323 jin. The county has reaped 360 million jin of wheat this year, marking an increase of 13.2 percent compared with 1981. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 18 Jul 82 OW]

ZONGYANG COUNTY EARLY RICE--By 25 July, Zongyang County, Anhui, had harvested 170,000 mu of early rice and planted over 100,000 mu of late rice. [OW100623 Hefei Anhui Provincial Service in Mandarin 1100 GMT 1 Aug 82]

LUJIANG COUNTY RICE HARVEST--Lujiang County in Anhui has reaped a bumper harvest from its 650,000 mu of early rice fields this year, with both total and per-mu yields hitting an all-time high. The average per-mu yield has reached 730 jin while the total output is 10 percent more than last year. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 9 Aug 82 OW]

PRCSPECT OF GOOD WHEAT HARVEST IN SUBURBS SEEN

Beijing BEIJING RIBAO in Chinese 24 Apr 82 p 1

[Article: "Wheat Growing Well on 2.5 Million Mu in Beijing Suburbs"]

[Text] After a brave fight waged jointly by the great number of cadres and commune members under the severe conditions of sustained dry weather and days without water, the wheat on 2.55 million mu in this city's suburbs is growing better than expected. If only the suburbs continue to economize in using water, rationally irrigate, and scientifically manage the fields, there is a great hope that they will achieve a good harvest of summer grain.

Last autumn, the people in the suburbs firmly implemented the policy of making planned economy primary and overfulfilled the state's wheat planting plan on a total acreage of over 2.553 million mu. However, the dry weather and lack of water, the insufficient soil moisture, coupled with a fairly early drop in temperature, caused the wheat on the greater part of the fields to grow weakly with little tillering and an insufficient total number of stalks before winter set in. According to statistics compiled at that time, third-grade seedlings accounted for 40 percent of the wheat in the suburbs.

Under extremely disadvantageous conditions, the communes and production teams in the suburbs, in line with the ideas of agricultural experts and scientific and technical personnel, got a tight grip on wheatfield management centered on resisting drought and protecting seedlings. After spring began this year, under conditions in which electric power was insufficient, the great number of communes members made no distinction between day and night and turned on the irrigation machinery during the power-supply periods. By the first part of April, over 90 percent of the wheatfields in the suburbs had been irrigated once and had received one application of fertilizer. In addition, the temperatures this spring have tended to be high and steady, and the frequent cold snap in spring of previous years has not occurred, which is even more advantageous for the growth of the wheat, and the greening and jointing of the wheat seedlings has on average occurred about 5 to 7 days earlier than in normal harvest years. Because the spring tillering stage is long, the insufficiency in the total number of stalks before winter set in has been made up, and the highest total number of stalks this spring is greater than in the corresponding period of last year. According to statistics, there are less than 30 percent third-category seedlings. This spring barley, planted on 350,000 mu, is also growing better than in the recent several years.

The municipal department concerned has pointed out: From now on water will be in even shorter supply, and a second watering of several tens of thousands of mu of wheat in the suburbs cannot be quaranteed. Therefore, it is extremely important to economize on water use and to irrigate rationally. Communes and production teams that have not yet put into practice the motor-pumped well responsibility system must quickly do so. The work of maintaining old wells and refitting deep-well pumps must continue to be done intensively. Owing to the fact that the wheat's growing stage is ahead of time, water and fertilizer must be applied early in the jointing stage. Although there are many difficulties, if management is done well in the middle and final stages a good harvest of wheat can be obtained.

PEASANTS PAPER SUPPORTS IDEOLOGICAL EDUCATION

HK240528 Beijing ZHONGGUO NONGMIN BAO in Chinese 1 Jul 82 p 1

[Contributing commentator's article: "Arm the Peasant Party Members With Communist Ideology"--slantlines denote boldface]

[Text] The central force leading our cause forward is the Chinese Communist Party. While we are warmly commemorating the 61th anniversary of the founding of the CCP, still fresh in our memory is what Comrade Hu Yaobang said 1 year ago at the meeting in commemoration of the 60th anniversary of the founding of CCP: "In the new historical period, faced with the great task of socialist construction for modernization centering on economic construction, we deeply feel that in order to fulfill this task, the key lies in our party." In the past year our party has continuously adhered to the Marxist ideological, political and organizational lines, put into effect a series of correct policies and guiding principles and devoted great efforts to education in party spirit, party style and party discipline, and made a number of improvements and progress in party style. Popular style is spurred by party style. As a result of the political stability and economic prosperity in our country, great changes have taken place in the mental attitude of the people. Especially in the vast rural areas, with the rapid development of production and improvement of people's standard of living, the peasants are full of joy and every place has a new look about it. The broad masses of peasants are on more intimate terms with the party. They pin their hopes on the party and are more confident in realizing the four modernizations.

Vast numbers of party members fighting in the countryside have played important roles in developing the excellent situation there. The vast majority of them love the party, love socialism and love the collective. They are able to unite and lead vast numbers of peasants in earnestly implementing the party's various policies and guiding principles and in making positive contributions to building material and spiritual civilization in the countryside. Nevertheless, we must also see that quite a number of grassroots party organizations and party members have not yet adapted themselves to the requirements of the new historical period. Some have the problems of impurity in ideology, style and organization. Some are weak and lax, caring nothing for the struggle against bad persons and bad deeds. A handful of grassroots party organizations and party members even take the lead in commiting crimes. All this seriously isolates the party from the masses, harms the prestige of the party and weakens the fighting ability of the party. It must be changed as soon as possible.

As early as 40 years ago, Comrade Mao Zedong said: "Many of our comrades do not know the difference between the Proletariat and the petite bourgeoisie. Many party members have joined the party organizationally, but they have not completely joined the party ideologically, or have not completely joined the party yet." In order to make the vast numbers of party members in the countryside and bring into full play their roles as pioneers and models by which they can lead and influence the masses of the peasant with their practical actions in uniting together for the realization of the party's line and objective, it is necessary to conduct complete and deep ideological education for the party members in the countryside so as to guarantee that the party ranks will better meet the requirements of socialist construction for modernization.

/It is necessary to conduct education in communist ideology./ The essential feature of a Communist Party member is that he must, politically, ideologically, in style and action, steadfastly maintain the natural color of a Proletarian vanguard, master dialectical and historical materialism, adhere to the four basic principles, and firmly embrace the communist world outlook. At present, some party members have lost their interest in Marxism-Leninism-Mao Zedong thought, and have strengthened their feelings for "money and currency." They have forgotten the great communist goals and are keen on their own cause. This is extremely wrong. We must realize that we party members are not only ordinary peasants, but also the members of the Proletarian vanguard. Therefore, we must keep the great communist goal in our minds and be concerned for the "great cause" of the party and people. We must correctly handle the relationships between the state, the collective and the individual. One's personal interests must be subordinated to the interests of the collective. Partial interests must be subordinated to overall interests. Present interests must be subordinated to long-term interests. We must unite the masses and have close cooepration with them in our labor, work and life, bring into play their initiative, enthusiasm and creativity, rely on the wisdom and strength of the collective to overcome various difficulties in marching forward and fight all our lives for communism. Many comrades who joined the party since the "great cultural revolution" lack basic communist awareness. Therefore, it is an urgent task to conduct relatively systematic communist ideological education for them.

/It is necessary to conduct education in the party's various policies and guiding principles in rural areas since the third plenary session/ because "leftist" influence has not yet been cleared away, plus the fact that there is no education or insufficient education being conducted, some party members in the countryside do not quite understand the party's rural line, guiding principles and policies since the third plenary session, or even adopt a resistant attitude toward them. Moreover, some only implement those regulations which suit their own tastes and do not implement those they dislike. All this directly causes bad influence and disruption to the implementation of the party's various rural policies and guiding principles. Therefore, it is necessary to continue education for the party members in the party's line, guiding principles and policies. Through education, vast numbers of party members will understand how our party formulates correct policies on the basis of closely integrating the scientific truth of Marxism-Leninism-Mao Zedong thought with the practical situation of our country, and why it is necessary at the present stage to implement these policies and understand their significance. They will also know how to understand and master the essence of the party's policies and consciously and creatively implement them in practice. At present, special attention should be paid to educating party members in earnestly studying the "minutes of the national conference on rural work" approved and transmitted by the central authorities and to unifying understanding, guiding action and promoting work according to the essence of this document.

/It is necessary to conduct education in party spirit, party style and party discipline./ At present, a handful of party members are carrying out religious, group, faction an superstitous and bambling activities. Some of them are even engaging in smuggling, corruption, robbery, speculation, fraud, bribery, and divulging and selling top secrets of the country. All these things have undermined party unity and discipline. Every party member must, through education, know that it is necessary to abide by the party constitution and the guiding principles for party political life and clearly understand the various expressions of the class struggle under the new historical conditions. Every party member must maintain the purity of the Communist Party and prevent the invasion and infiltration of decadent capitalist ideology and lifestyle, thus building a great wall for consciously resisting capitalist ideology. In multi-nationality areas, it is also necessary to conduct education for the party members in nationality policies, the unity of nationalities, and atheism.

"Ideological education is the key link to be grasped in uniting the whole party for great political struggles. Unless this is done, the party cannot accomplish any of its political tasks." (Mao Zedong: "On Coalition Government") We must, in accordance with this instruction of Comrade Mao Zedong and proceeding from practice, widely, incessantly and deeply conduct ideological education for the vast numbers of party members in the countryside, arm them with communist ideology, and greatly upgrade their communist awareness and their awareness of party spirit, organization and discipline. By so doing, they can faithfully fulfill their solemn pledge when they joined the party and always remember that is is our party's objective to serve the people wholeheartedly, it is our party's ultimate aim to realize communist ideal and that party members must fight for communism all their lives. They must bring into full play their roles as vanguards and models in various tasks and be rooted among the masses of the peasants. They must guarantee that the party's policies and guiding principles be implemented in the grassroots and vigorously mobilize a mighty force to make greater contributions for building a modern, highly democratic and highly civilized socialist new countryside.

CSO: 4007/511

PRODUCTION BRIGADES LOOK AFTER ELDERLY PEASANTS

OW050906 Beijing XINHUA in English 0717 GMT 5 Aug 82

[Text] Beijing, 5 August (XINHUA)--More than 426,000 elderly peasants are now enjoying old-age pension paid by their collectives in 11 Chinese provinces and municipalities, according to a spokesman of the Ministry of Agriculture, Animal Husbandry and Fishery.

The pensions are offered by 3,400 prosperous production brigades in these provinces and municipalities (a production brigade is a collective work unit consisting of one or more villages with scores to hundreds of peasant families). Peasant men aged 65 and over and peasant women over 60 are granted pensions, provided they have worked in the collectives more than 10 years. Generally, an old peasnat man or woman receives a monthly pension of 10 to 15 yuan and, in some areas, receives as mush as 20 yuan a month.

Following the Chinese tradition, pensioned peasants still live with their children who support them as before.

The 11 municipalities and provinces include Beijing, Shanghai, Tianjin, Zhejiang, Jiangsu, Shandong and Liaoning. The pensions are drawn by the production brigades from profits of their collective enterprises, sideline occupations or from their public welfare fund.

In the Huaxi production brigade of Jiangyin County, Jiangsu Province, the 107 peasant pensioners are provided with free food and fuel and supplied with five yuan a month per person. In terms of real income, the monthly pension comes to more than 20 yuan for one person.

Obviously hale and hearty, 80-hearty-old Qu Jiabao and his wife live in a large family comprising four generations. Qu Jiabao said he and his wife are not lonely, looking after their three-year-old great grandson, and are delighted to watch the child toddling about and playing lively.

Some old peasants in the Huaxi production brigade spend their time in raising checkens and rabbits, planting flowers or playing chess. In the brigades newly built 200-seat theater, the eight front rows have sofas and tea tables especially prepared for the aged.

Among the 107 old peasants in the Huaxi production birgade, over 30 have asked to join in collective labor since they are in good health. The leaders assign light jobs to them and pay them for their work in addition to their pensions.

More than 120,000 old peasants have been granted pensions in the suburbs of Shanghai, where the number of pensioned peasants ranks first in China.

Output of grain and economic crops in the ten suburban counties of Shanghai is among the highest of the country for years and, since mid-1970s, most of suburban communes and production brigades have expanded handicrafts, fishery and other side-line occupations, which bring forth over half of the total agricultural income.

In China, respect for the old, an age-old tradition, is also taken as a socialist morality. Old people with no close relatives to look after them in the countryside are entitled to "five guarantees"--food, clothing, housing, medicare and funeral expenses to be provided by the collectives. Some well-off communes or production brigades have also set up homes for the aged.

CSO: 4020/154

BRIEFS

CENTRAL METEOROLOGICAL BULLETIN--The Central Meteorological Observatory issued a strong typhoon bulletin at 0600 [2200 GMT] on 27 July: This year's typhoon No 9 was spawned over the northwestern Pacific on 22 July. At 0500 [2100 GMT] on 27 July, the typhoon was located about 1,000 km off the eastern part of China's Taiwan Province, or 18.8 degrees north latitude and 129.9 degrees east longitude. Maximum winds at the center of the typhoon are force 12. It is expected that the center of the typhoon will continue to gradually move in a northwesterly direction toward China's Taiwan Province at a speed of about 25 km per hour. Winds of forces 6 to 9, caused by the typhoon, are expected on 27-28 July over the eastern part of Taiwan Province, the Balingtan Channel and the Bashi Channel. Strong winds of forces 10 to 12 are expected along the path of the typhoon. It is requested that all units concerned tune in to weather forecasts broadcast by local meteorological stations. COTTON PURCHASE--Beijing, 25 Jun (XINHUA)--China's commercial departments purchased 2,875,000 tons of cotton by the end of May, an all-time high, according to a national conference that opened here today. The figure represents an increase of 200,000 tons over the 1980 purchase year. The 1981 domestic purchase year starts September 1981 and ends in August 1982. Purchase quotas were topped in the country's major cotton producing centers of Shandong, Jiangsu, Anhui, Hebei, Henan, Xinjiang, Liaoning, Hunan and Jiangxi. The increase helps provide more raw materials for the textile industry and reduces the need for cotton imports. [Text] [Beijing XINHUA in English 0707 GMT 25 Jun 82 OW]

BRIEFS

LONGYAN PREFECTURE RICE PRODUCTION--Longyan Prefecture, Fujian, has reaped a good harvest of 84,000 mu of early rice, with its per-mu yield reaching as high as 534 jin. The prefecture has also planted 720,000 mu of paddy rice of a disease-resistant strain, and greatly reduced incidents of rice blast. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 23 Jul 82 OW]

FUJIAN PREFECTURES' EMERGENCY HARVEST--As an emergency measure against this year's typhoon No 9, on 26 July, Fujian's Putian Prefecture reaped harvest from 200,000 mu of early rice paddies and on 27 and 28 July, Jinjiang Prefecture reaped 70,000 mu and Longxi Prefecture 100,000 mu of early rice. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 30 Jul 82 OW]

FUZING COUNTY CROP LOSS--About half the 140,000 mu of potatoes in Fuzing County, Fujian, were damaged by this year's typhoon No 9. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 3 Aug 82 OW]

HUIAN COUNTY TYPHOON DAMAGE--About 150,000 mu of Huian County's 210,000 mu of potatoes in Fujian were damaged to various degrees by this year's typhoon No 9. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 4 Aug 82 OW]

SANMING PREFECTURE RICE--Despite adverse weather, Sanming Prefecture, Fujian Province, has reaped a bumper harvest of early rice in this year. The total output of early rice reaped on the prefecture's 1.4 million mu of rice fields was 740 million jin, or 23 percent more than 1981. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 5 Aug 82 OW]

LONGXI PREFECTURE EARLY RICE--Longxi Prefecture, Fujian Province, has scored a bumper harvest from its 1.7 million mu of early rice fields with a per-mu output higher than last year. Total output reported by Zhangzhou municipality and Changtai, Yunxiao, Nanjing, Pinghe and Huaan Counties all topped last year's records, the increase ranging from several hundreds of thousands to some 4 million jin. ANIMAL HUSBANDRY--Guangdong achieved all-round development in animal husbandry in the first half of the year. The number of pigs at the end of June showed an increase of 880,000 over the figure for the beginning of the year, a rise of 4.6 percent. Total pork procurement increased by 15.87 million jin, a rise of 5.9 percent. The number of cattle increased by 335,000, a rise of 8.4 percent. The province now has 100,000 households specializing in raising poultry or rabbits. Some households have raised more than 100 pigs or several score cattle. HAILUN EXPLORES AGRICULTURAL MODERNIZATION

OW031319 Beijing XINHUA Domestic Service in Chinese 0021 GMT 3 Aug 82

[Report by XINHUA Correspondents Sun Minghui, Jing Bo and Wang Changkuan]

[Excerpts] Harbin, 3 Aug (XINHUA)--HINHUA editor' note: What after all is the Chinese way of agricultural modernization? For some time people have done numerous theoretical studies on the subject. Now, Hailun County has made some valuable practice exploration.

Speaking of agricultural modernization, some people's first thought is to invest a lot of money, import complete sets of advanced equipment and one-sidely pursue "modernization" in one way or another. Judging from our country's actual conditions, our agriculture in the future will probably be of the labor-intensive and knowledge-intensive type, not the high energy consuming or highly automated type of agriculture. Proceeding from actual local conditions, Hailun County has taken a road of agricultural development characterized by relying mainly on biological measures; combining biological measures with mechanical measures and other technical measures; all-round development of farming, forestry, animal husbandry and sideline production; engagement in integrated agricultural-industrial-commercial operations; and mutual promotion of science, education and economy. Without much investment and without consuming huge amounts of energy, this road may lead to the initial achievement of what experts regard as agricultural modernization's two goals: to improve the agroecological system and to develop agricultural production in all-round way. Of course, our country has a vast territory and natural and social conditions differ greatly. The Hailun County experience is born on the soil of the Song-nen Plain. With people practicing and exploring, more broad roads will be found for our country's agricultural modernization. (End editor's note)

Hailun County, Heilongjiang, has conducted scientific experiments in agricultural modernization for only 3 years, and not only have gratifying changes taken place in the whole county's agricultural production and ecological system, but a road to develop agriculture has been initially found which requires little investment, shows quick results, yields high returns and gives real benefits to peasants. The county has gained important experience in exploring a road toward a Chinese way of agricultural modernization.

Hailun County is located on the Song-nen Plain in central Heilongjiang and, climatically, it belongs to the temperate zone. The land is fertile and rainfall is quite plentiful. The per capita acreage of farmland in the county is five mu. The natural conditions for agricultural production are quite good. Since the late 1950's however, due to the influence of "left" thinking, forests and grasslands here were destroyed to reclaim farmland and, as a result, there was increasing ecological deterioration and frequent natural disasters, and agricultural production growth was slow, per mu grain output increasing by only a few dozen jin in more than 20 years.

In 1978, the Heilongjiang Provincial CCP Committee and the Chinese academy of sciences organized more than 100 agricultural specialists and senior and middle-level scientific research and teaching personnel to conduct comprehensive scientific experiments for agricultural modernization together with Hailun County's cadres and masses. In only 3 years the situation has changed. Comparing the average figures for the 3 years between 1979 and 1981 when scientific experiments in agricultural modernization were being conducted with the 3 years before the experiments, total grain output increased by 14 percent, marketable grain sold to the state increased by 35.9 percent, the total agricultural output value increased by 22 percent, and other farm and sideline products, such as hogs, cattle, sheep, milk, beets and flax increased by even greater margins. Collective accumulation and commune members' income also showed great increases.

In conducting scientific experiments for agricultural modernization, the agricultural specialists and the Hailun people have focused their work on "adapting to China's conditions" and especially on "adapting to the conditions of the Song-nen Plain in northeast China," and broken away from many of the old ideas on agricultural modernization.

First, whenever people talked about agricultural modernization in the past, many felt that it could not be done without heavy investment. Since Hailun County began conducting scientific experiments in agricultural modernization, it has never asked the state for extra investments, nor has it received more bank loans than the average level received by all counties in Heilongjiang. Mainly by rationalizing the production structure, which resulted in considerable improvements in the ecological environment and production conditions, and simultaneously bringing into full play the role of advanced agricultural technology, agricultural development has been accelerated.

Second, whenever people talked about agricultural modernization in the past some wanted to import a lot of advanced equipment or simply concentrate on engineering and construction, one-sidedly pursuing "modernization" in one way or another. Hailun County has proceeded from actual conditions and adopted the practice of combining biological measures with mechanical measures and other technical measures, with empahsis on biological measures.

Based on the agricultural specialists' recommendations, Hailun County has vigorously readjusted the proportions between agriculture, forestry and animal husbandry and within agriculture itself, and accelerated the development of the two "short legs": Forestry and animal husbandry. Beginning in 1979, they have carried out three major readjustments in crop patterns according to local conditions turning more than 400,000 mu of scientifically unsuitable grain fields into fields growing cash crops--mainly soybeans, forage grass and other forage crops. At the same time, they have actively planted trees under a unified plan according to needs, including water and soil conservation forests on tracts of sloping farmland and shelter forests in selected areas on vast stretches of flat land, and distributed lowlying lands to commune members to grow trees for fuel. In 3 years, the county has afforested 200,000 mu of land, over 50,000 mu more than the total area afforested in the previous 28 years. During the same period, animal husbandry has also grown correspondingly. As of the end of 1981, the county's sheep, milch goats and milch cows increased 5 to 15 times the numbers in 1978.

Hailun County emphasizes biological measures, but it does not ignore the adoption of mechanical measures and other technical measures. In the past few years, they have selectively bought more than 400 large and medium-sized tractors and more than 2,000 hand-guided tractors on the basis of requirements and affordability.

Third, when people talked about agricultural modernization in the past, they often only gave consideration to the adoption of new technology. While adopting technical measures, Hailun County has also paid attention to reforming the economic structure, stressed scientific management and strived for the greatest possible economic results.

To achieve agricultural modernization, it is imperative that commodity production is developed. In the past few years, Hailun County has paid attention to developing processing industries using farm and sideline products as raw materials, enlivening circulation channels and building a rational economic system which consists of cropping, breeding, processing and integrated agricultural-industrial-commercial enterprises while regarding this as an important part of agricultural modernization.

Fourth, Hailun County has paid great attention to the important role of tapping the intellectual resources in carrying out agricultural modernization. They hold that "without first rate technically competent peasants, there can be no first rate modern agriculture." Here, many communes and production brigades are willing to spend money on training competent people. The county is presently running a rural construction school for the rotational training of technicians and commune and brigade cadres, and the communes and production brigades have generally set up technical training classes or technical night schools. As many as 100,000 young and middle-aged people, more than a half of the country's young and middle-aged peasants, are regularly studying at these classes and schools. More than 10,000 peasant-technicians have received training. They are active on the production frontline and in scientific experiments and have become the backbone force in agricultural modernization.

BRIEFS

DAIRY FARMING--Harbin, 26 Jul (XINHUA)--Heilongjiang Province has become China's largest dairy products center, following the establishment of dairy cattle farms in 60 cities, counties and state farms since 1979, according to the provincial light industrial department. The province produced 11,500 tons of dairy products in the first half of this year, a 35.2 percent increase over the same period in 1981, the department reported. The products include powered and condensed milk, butter and cream. Last year the province's output of dairy products came to 18,500 tons, 110 percent more than in 1978. The department attributed the increase to encouraging rural collective units and individuals to raise milk cows and increasing the purchasing price for fresh milk. With 3.33 million hectares to grasslands and pasture land, Heilongjiang now has 114,000 head of milk cows, 83.9 percent more than in 1978. [OW281203 Beijing XINHUA in English 0243 GMT 26 Jul 82]

TIMBER OUTPUT--Forestry areas in Heilongjiang Province have made progress in producing timber from tree branches. In the first half of 1982, the province turned out 262,900 cubic meters of timber of this kind, a more than 148,000 cubic meter increase over the output of the corresponding 1981 period. [SK251020 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 23 Jul 82]

SOYBEAN PROCESSING PLANTS--Three self-designed and self-constructed soybean processing plants were recently commissioned in Harbin, Qiqihar and Jixi Municipalities. The three large-sized modern soybean processing plant have a combined daily processing capacity of 480 tons of soybeans. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 22 Jul 82 SK]

PROLONGED HIGH TEMPERATURE--Heilongjiang Province's summer high temperature arrived early this year and continued longer than usual, breaking a 30-year record for this period. Coupled with high temperature was weather characterized by little rain, dry hot air, low humidity and rapid evaporation, which definitely affected industrial and agricultural production and peoples' lives. On 10 July, the provincial weather bureau predicted that high temperatures will continue until after mid-July and rain precipitation will increase in various areas in the province beginning late July. Temperatures will also fall by then. The weather bureau attributed the consistent high temperature to a prolonged high pressure in Central Asia and a warm air mass moving eastward from Qinghai-Tibetan Plateau. High temperatures and low precipitation were the main characteristics of this summer's weather in Heilongjiang, according to the provincial weather bureau. BRIEFS

PREFECTURE'S GRAIN PROCUREMENT--By 28 June, Nanyang Prefecture had stored 585.04 million jin of summer grain in granaries. Deng, Tanghe, Sheqi, Xinye and Zhenping Counties and Nanyang Municipality have overfulfilled their grain procurement quotas for this year. Deng and Tanghe Counties have stored more than 100 million jin of summer grain in granaries. Every person in Sheqi County sold an average of 148 jin of grain to the state. [Zhengzhou Henan Provincial Service in Mandarin 1130 GMT 1 Jul 82 HK]

NATURAL PROTECTION ZONES--To protect rare wild animals and develop and utilize natural resources, the Henan Provincial People's Government recently decided to set up 13 natural protection zones in the province. These 13 natural protection zones are 12 state-owned forest zones in Song, Xixia, Luanchuan, Lushan, Nanzhao, Shangcheng, Xin, Luoshan, Tongbai, Xinyang, Jiyuan and Lingbao counties and 1 collective forest zone in Jiyuan County. The total area of the natural protection zones is 1.278 million mu. Wild animals and plants abound in these natural protection zones. [Zhengzhou Henan Provincial Service in Mandarin 1130 GMT 1 Jul 82 HK]

GRAPE PRODUCTION BASES--The Henan Provincial CCP Committee and the provincial people's government recently decided to build 1 million mu of grape production bases in 18 counties in Shangqiu, Kaifeng, Zhoukou, Anyang and Xinxiang Prefectures and in the suburbs of Zhengzhou and Kaifeng Municipalities. They have also planned to build a fermentation township in every 5,000 mu of vineyards and a brewery in every 30,000 mu of vineyards. The motion on building grasp production bases was put forward by Dai Suli, secretary of the provincial CCP Committee and governor and He Zhukang, vice governor. According to the plan, the province will now begin to make preparations for building 1 million mu of grape production bases and will complete this work by 1985. It is estimated that the average annual output of grapes per mu will be 1,500 jin, and as the price of every jin of grapes is .25 yuan, the income from 1 million mu of vineyards will be approximately 400 million yuan. [HK090245 Zhengzhou Henan Provincial Service in Mandarin 1130 GMT 1 Jul 82]

BRIEFS

PIGS--Pig production revived and developed in Hubei during the first half of the year. According to statistics, the number of pigs in the province at the end of June exceeded 15 million, an increase of 160,000 compared with the same time last year. Stocks of pork have greatly increased in Wuhan, Huangshi, Shiyan, Shashi and Xiangfan Municipalities. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 23 Jul 82 HK]

PEASANT INVESTIGATION--The provincial statistics bureau recently investigated the domestic economic conditions of 948 peasant households in various counties. The investigation showed that their average cash income per individual in the first half of the year was 93 yuan, an increase of 32 yuan over the same period of last year, while average cash expenditures per individual were 94 yuan, an increase of 31 yuan. Cash income from their sales of agricultural, forestry, animal husbandry, sideline products and fisheries produced average 35 yuan per individual, an increase of 10 yuan compared with the same period last year, while they spent an average of 72 yuan per individual on buying industrial products, an increase of 25 yuan. BRIEFS

HUNAN GRAIN CROP HARVEST--Hunan Province reaped a bumper harvest of 1982 spring-summer harvested grain crops. According to the estimate by the concerned departments, the total output of these crops increased by 5.9 percent over 1981's. Hunan Province's major spring-summer harvested grain crops are wheat, broad beans, peas and potatoes. After planting some of these crops last winter, various locations strengthened cultivation management and applied overall mud fertilizer. As a result, the kernels are full and healthy, increasing the weight by the thousands of kernels. The total output of spring-summer harvested grain crops in Changde, Lianyuan, Yueyang and other prefectures is 10 percent higher than 1981's. [Beijing BEIJING RIBAO 15 Jul 82 p 4]

EFFORTS MADE TO RAISE FARM YIELDS IN HU-HUAI AREA

Beijing ZHONGGUO NONGMIN BAO in Chinese 9 May 82 p 1

[Article: "Bring Out the Potential for Increased Output of Medium- and Low-Yield Areas:]

[Text] Suiting measures to local conditions, the Xu-Huai area in Jaingsu Province has extensively popularized experience in intensive cultivation of high-yield areas and has brought out the potential for increased output of medium- and low-yield areas. Last year the total grain output was 15 percent higher than in the big harvest year of 1979, and in some places the level of intensive cultivation approached or exceeded that of southern Jaingsu.

The Xu-Huai area in northern Jaingsu roughly includes the three prefectures of Xuzhou, Huaiyin, and Yancheng. At the time of liberation, it was a dry grain crop area and very little paddy rice was planted. Water conservancy projects were built at the beginning of the 1950's and paddy rice production was not high. In 1978 it was no more than 300 to 400 jin, and was much lower than in the high-yield areas of southern Jiangsu. The reason for this was that field cultivation and management were relatively extensive. For this reason, the leaders at all levels in the Xu-Huai area paid much attention to the experience of high yields in southern Jiangsu and, suiting the experience to local conditions, popularized it.

After the 3d Plenary Session of the 11th CCP Central Committee, because the production responsibility system was set up on a widespread scale and was being continuously perfected, the demand by the peasants in the Xu-Huai area to learn intensive cultivation techniques became more imperative. This area is suitable for rational crop rotation, viz, 2 crops in 1 year consisting of rice and wheat, and 3 crops in 2 years consisting of rice, wheat, and green fertilizer. Over the past several years, there has been extensive popularization of Suzhou Prefecture's measures of intensive cultivation, viz, breeding sturdy seedlings, leveling land, having one irrigation ditch and one earth bank, straining salt through water, and using fertilizer to repress alkali, so that in the Xu-Hua area the acreage of paddy rice has been expanded by an average of about 1 million mu a year. In 1979, the per unit area yield of paddy rice in Huaiyin Prefecture was 400 jin; last year the 500 jin barrier was broken. The total grain output of the three prefectures last year was the highest in history and was 2.8 billion jin more than in the big harvest year of 1979. Last year Huaijin Prefecture increased its grain output by 1.4 billion jin. With the increased grain output and the development of a diversified economy, the income of the peasants has risen rapidly and their life has continually improved. In Sihong County, the average income distribution rose from 42 to 121 yuan, and in Xuyu County it rose from 60 yuan to 173 yuan.

The large-scale agricultural output increase in the Xu-Huai area guarantees a province-wide growth in agricultural output. Supported by the provincial party committee and the departments concerned, the peasants adopted the following relatively useful measures.

1. Cadres from agriculturally advanced areas have been transferred to the Xu-Huai area, and in its thinking the leadership has attached importance to the popularization of advanced experience. At present, the princial responsible persons on the party committees of the three prefectures are persons who had been transferred from southern Jiangsu, and once 50 communes secretaries were transferred at one time.

2. Agrotechnical cadres from southern Jiangus have been invited to come to the Xu-Huai areas and pass on experience, or the Xu-Huai area has sent technicians and cadres to southern Jiangsu to study and to actively take part in the province's annual agrotechniques exchange activities between the northern and southern areas of Jiangus. Also, every year Chen Yongkang [7115 3057 1660], a peasant paddy rice expert, is invited to come to northern Jiangsu to help solve problems encountered in paddy rice production.

3. In academic thinking, the strategic significance of developing the Xu-Huai is clearly recognized. Last year, the provincial scientific and technological association organized over 90 experts and scholars from 14 learned societies--including those on agronomy, water conservancy, forestry, soils, weather, silkworm mulberry, aquatic products, and animal husbandry--to go to the Xu-Huai area and conduct on-the-spot investigations. After comprehensive analyses, they proposed that the Xu-Huai area be built into a base for the production of diversified agricultural commodities.

COMMENTARY ON DEVELOPING MEDIUM-, LOW-YIELD AREAS

Beijing ZHONGGUO NONGMIN BAO in Chinese 9 May 82 p 1

[Article: "Vigorously Develop Medium- and Low-Yield Areas"]

[Text] According to statistics compiled by the departments concerned, high-, medium-, and low-yield areas each roughly make up one-third of the country's cultivated land. In per unit area yield, the highest for grain is over 1 ton and for ginned cotton several hundreds of jin; the lowest for grain is several tens of jin and for cotton between 10 and 20 jin. The differences are extremely large. Therefore, the problem of how to bring out the potential of medium- and low-yield areas has drawn people's attention more and more.

In medium-yield areas, more often than not the natural conditions are good and there is adequate technology, and so long as these areas are conscientiously developed the production features can swiftly change. At present, they are the areas where there is the greatest potential for increased production. The experience of Xu-Huai were, first, the masses were enthusiastic; second, the leadership was determined; third, the technical personnel played their role; and fourth, attention was paid to suiting measures to local conditions. This suiting of measures to local conditions was very important. It is possible that in medium- and low-yield areas there are high-yield communes and production teams, and it is also possible that in medium- and low-yield communes and production teams there are high-yield plots. Therefore, while introducing advanced experiences from outside, a given locality must sum up its own advanced experiences and learn from others' strong points to offset its own weaknesses in order to obtain better results.

Of course, while developing medium-yield areas, we must also get a good grip on high- and low-yield areas. High-yield areas have always made big contributions to the state. To maintain high and stable yields, and to work hard for increases amid stability--this is what high-yield areas should be able to do. And although it is difficult for the low-yield areas where production conditions are very poor to suddenly catch up with the high-yield areas, they must summon up their spirits and, on the foundation of solving the problems of their people having enough to eat and wear, strive hard to improve their production conditions and do all they can to change the features of production as quickly as possible.

BRIEFS

RICE MEETINGS--Recently the Jiangsu Provincial Agricultural and Forestry Department held meetings on paddy rice field management in Jianhu and Yancheng counties. Attending the meetings were nearly 100 leaders and technical cadres in charge of rice production. They pointed out that this year Jiangsu has only 36.4 million mu of double-cropped paddyfield, or some 900,000 mu less than last year, and this, plus other problems such as plant diseases, insect pests and insufficient supply of chemical fertilizers will make it a not easy task to achieve a bumper harvest this year. For this reason, they said, all-out efforts should be made to strengthen field management so as to overcome the difficulties and ensure a good harvest. [OW010456 Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 3 Jul 82]

COTTON MEETINGS--The Jiangsu Provincial Agricultural and Forestry Department recently held on-the-spot meetings in Dongtai and Judong Counties on management of cotton fields. Comrade Zhou Ze, secretary of the provincial CCP Committee and concurrently vice governor of the province, addressed both meetings. The meetings stressed the necessity to strengthen cotton field management with particular attention to controlling cotton diseases and insect pests. This year Jiangsu Province has nearly 10 million mu of cotton, which, according to the meetings, are in fine growing condition. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 14 Jul 82 OW]

HUAIYIN COUNTY WHEAT PRODUCTION--Huaiyin County, Jiangsu, reaped more than 174 million jin of wheat, barley and naked barley this summer, an increase of 20 percent over last year. The county's total rapeseed production amounted to 10 million jin, about 200 percent higher than last year's output. [OW100627 Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 3 Jul 82]

JIANGSU SUMMER GRAIN PROCUREMENT--Jiangsu Province made a breakthrough in summer grain procurement. The province has procured 5 billion jin of summer grain, overfulfilling the quota ordered by the state by 56 percent. This is unprecedented in the province's summer grain procurement history. BRIEFS

GRASSLANDS IMPROVEMENT URGED--The animal husbandry general bureau of the Ministry of Agriculture, animal husbandry and fisheries held an on-the-spot meeting on grassland improvement in Daan County in Jilin Province on 23 July. Grassland experts from various provinces visited Daan County's pastures. The usable grassland in Daan County declined from 4.26 million mu in 1949 to 2.25 million mu in 1982. The rate of increase of draft animals decreased from 15 percent in the 1950's to 2 percent in 1982. To divert grassland degeneration, the county added 440,000 mu of man-made pastures and planted 13,000 mu of grass and recently decided to plant grass on 150,000 mu of alkaline land. [SK260550 Changchun Jilin Provincial Service in Mandarin 1100 GMT 25 Jul 82]

WHEAT OUTPUT--Bayannur League, Nei Monggol autonomous region, is expected to reap a bumper wheat harvest this year. As of 19 July, the league had harvested over 200,000 mu of wheat crop. In 1982, the league sowed over 1.8 million mu of wheat, a 125,000 mu increase over the 1981 acreage. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 Jul 82 SK]

LIVESTOCK OUTPUT--Ju Ud League, Nei Monggol autonomous region, has reaped a bumper harvest in animal husbandry this year. The league has had 6.72 million head of animals, a 300,000 head and 22.9 percent increase over the 1981 figure. Meanwhile, Jirem League has also scored achievements in raising cattle. The league has 925,057 head of cattle, a 67,846 head increase over the 1981 figure. Since 1981 Jirem League has sold 77,054 head of cattle to the state and exported 24,000 head of cattle. [SK250800 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 Jul 82]

ANIMAL HUSBANDRY--Alxa League, Nei Monggol region, witnessed productive camel breeding in the first half of 1982. The total number of camels reached 251.475 head, the highest figure in history. This league has also allocated 85.88 million jin of fodder grass to feed camels and transferred 34,000 head to grazing in other localities. [SK270654 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 Jul 82]

ANIMAL HUSBANDRY--Xilin Gol League, Nei Monggol region, experienced productive livestock breeding in the first half of 1982. The total number of livestock reached 7,819,000, an increase of 670,000 head or 30.8 percent. The total number of livestock in Bayannur League reached 1,725,000 in the first half of 1982, an increase of 170,000 head. Ju Ud League sheep breeding farm has turned out 87,540 head of fine wool sheep and 2,561,700 jin of fine wool to the state in the past 23 years since its founding. [SK260215 Hohhot Nei Mongool Regional Service in Mandarin 1100 GMT 25 Jul 82]

LIVESTOCK OUTPUT--Jirem League in Nei Monggol autonomous region scored remarkable achievements in livestock production in the first half of 1982. According to statistics, the league had over 3,581,500 head of young and grown animals, an over 695,200 head increase over the number of the corresponding 1981 period. While registering increases in the number of sheep and cattle, the league has also increased output in raising hogs since June 1981. By the end of June, the league had over 1,668,600 heads of hogs. [SK220408 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 21 Jul 82]

ANIMAL HUSBANDRY--Alxa League, Nei Monggol region, has witnessed productive livestock breeding in 1982. The total number of livestock reached 1,875,867 head, an increase of 275,861 head above plan. [SK031128 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 1 Aug 82]

GRASS PLANTING--Taking advantage of the rainy season, Nei Monggol is speeding up grass planting. So far the region has planted 1.5 million of grass. The region plans to plant 3 million mu of grass this year, about 1 million mu more than 1981. [SK280555 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 27 Jul 82]

BRIEFS

LIVESTOCK BREEDING--Yinchuan, 27 Jul (XINHUA)--The Ningxia Regional Animal Husbandry Bureau reports that the total number of sheep and large farm animals has increased in the stockbreeding year of 1982 (June 1981--June 1982). Ningxia region, one of China's major pastoral areas, was hit by sandstorms, snowstorms and a dry spell last winter and this spring. There has not been a saturating rain since January this year in the area, yet the number of sheep was up by 13 percent over last year's livestock totalling 3.27 million. The number of large farm animals used for hauling, including cattle, horses, donkeys, mules and camels, rose by 5.6 percent from last year's 570,000. The new production responsibility system was first put into practice in the region in 1980, and since then herdsmen have taken particularly good care of the sheep for which they were personally responsible by contract. The lambing rate and survival rate all have increased since then. [Text] [OW281205 Beijing XINHUA in English 0747 GMT 27 Jul 82]

BRIEFS

FARM-MACHINE SALES INCREASED--In the first half of 1982, sales in farm machinery throughout Shandong Province reached more than 446,711,000 yuan, topping the peak of the previous period. The sales of farming power, drainage and irrigation machinery increased 62 percent over the figures of the corresponding 1981 period. This year the province has enjoyed brisk sales in small-sized and semi-automatic machines. [SK240609 Jinan Shandong Provincial Service in Mandarin 2300 GMT 22 Jul 82]

TOBACCO OUTPUT--In spite of a serious drought, Shandong Province has reaped a bumper harvest this year over its more than 1.5 million mu of tobacco crops. As of 21 July, the province had procured over 420,000 dan of tobacco leaves, over a 3-fold increase over the output of the corresponding 1981 period. The government also grants an 8-yuan increase per dan in the procuring price. [SK250804 Jinan Shandong Provincial Service in Mandarin 2300 GMT 24 Jul 82]

SICHUAN ISSUES NEW RURAL ECONOMY REGULATIONS

HK261401 Chengdu SICHUAN RIBAO in Chinese 14 Jul 82, pp 1, 2

[Report: "Provincial CCP Committee and Government Lay Down 10 Policy Regulations to Suit the New Situation and Speed Up Rural Economic Development"]

[Text] The Sichuan Provincial CCP Committee and the Sichuan Provincial Government, issued, on 29 June, the "policy regulations on certain questions concerning speeding up our province's rural economic development." The document read:

In order to speed up rural economic development in our province, while continuing to implement a series of effective policies laid down by the central authorities and by the provincial committee, it is necessary to adopt some policies and measures which are suited to the new conditions. After thorough discussion in the work meeting of the provincial committee, the provincial CCP Committee and the provincial government have made the following policy regulations.

1. In the course of implementing the "two systems" in forestry, localities, wherever conditions permit, should all appropriately increase private mountains assigned to peasants. Barren hills, waste hillside land and scattered plots which are not suited to collective management should be assigned to peasant households for planting trees. The collectives will maintain land ownership while woods and trees should be owned by the peasants and can be inherited. It is necessary to energetically encourage peasants to develop small orchards, mulberry fields, tea plantations or plant other economic woods on scattered plots, private hills and other plots specified by production teams. Income from these operations should belong to the peasants. This should remain unchanged for a long time to come. The state and the collectives should actively support peasants by providing seedlings and technical guidance. Whole tracts of woods owned by the collectives should be subject to the system of "four-specialization and one-contract." Economic woods around farmland should be contracted to the peasants together with the farmland. Measures like combining unified management with separated management, laying down quotas for income turned over to higher authorities in contracts and sharing out income in certain proportions, should be adopted, so as to allow direct operators to earn more if they yield more. Waste hillside plots suited to be handled by collectives can be handled by special teams and groups organized by production teams. They can also be assigned and contracted to peasant households for planting trees. Once the contracts are fixed, they will be kept for a long time to come. Gains

should be shared out between the collective and the peasant, with a large portion retained in the hands of the peasant.

2. The conservation of state-owned forests which the state is not able to manage and conserve can be contracted to local production teams and reasonable remuneration should be give to these teams. The trees planted along railroads, highways, rivers and canals and around reservoirs should be carefully protected. Units in charge of the areas along railroads, highways, rivers and canals or around reservoirs can plant trees and own the trees in these areas. They can also plant trees by cooperating with local communes and teams, with gains shared out among the parties concerned. The nearby communes and teams can also afforest these areas after the departments in charge agree. In that case, forests are owned by communes, teams or peasants, but tree-felling must be conducted in accordance with the regulations concerned laid down by the departments in charge.

3. In mountainous areas, capital construction of farmland must be stepped up to increase per area unit yeild. It is first necessary to guarantee a stable growth in gross grain output. At the same time, fields on steep slopes where farming should gradually give way to forestry or animal husbandry can be specified as reserve land by the production teams and contracted to special groups and households for planting trees and grass. As for those which have been contracted to peasants as "responsibility fields," as long as the accomplishment of assignments laid down by higher authorities is guaranteed, contractors can plant trees on these fields which are contracted to them for a long time and keep the gains for themselves. Or as alternative, collectives can provide seedlings to contractors or offer certain rewards, while gains are to be turned over to the collectives according to the quotas or shared out with a large proportion going to the peasants.

4. The provincial party committee decided in 1980 that, from 1981 on, "the provincial financial department will allocate 15 million yuan a year to remote areas, including the remote mountainous areas, as subsidies to the communes and teams there for planting 1 million mu of rapid-growing high-yield commercial forrests." In the same year, the provincial government issued a document and made concrete plans for this. This is an important policy for speeding up forestry construction in remote areas of our province. It has won popular support. The department concerned has carried out an inspection on last year's implementation and this year's plan and arrangement. They have resolved some problems, so as to guarantee the continual implementation of this policy. The forestry funds and development funds should be confined to being used for afforestation. Their use for other purposes is prohibited.

5. In 1980, the provincial party committee decided to offer 395 million jin of grain subsidies to support the rehabilitation of communes and teams in mountainous areas, impoverished areas and minority nationality regions, so that they could readjust agricultural structure and develop production. Practice has proved that this is effective. The original plan was to carry out this measure for a period of 3 years. Now, it is decided to extend the time to 1990. Quotas of grain subsidies distributed by the provincial authorities to prefectures, municipalities and autonomous prefectures will remain unchanged. But prefectural

and municipal authorities can appropraitely adjust quotas they issue to counties on the basis of rationalizing the use of these subsidies to suit the changed conditions in production development. The same goes for county authorities to communes and teams. These grain subsidies should be unifiedly arranged by county authorities. They should be mainly used for offsetting the reduction in grain purchase from the production teams where farming is giving way to forestry and animal husbandry or grain output is low and where grain is in short ration. The grain subsidies can also be used to subsidize the construction of bases for forestry, animal husbandry and other diversified undertakings. Generally, the purchase of agricultural, sideline and native products should not be linked with grain.

6. In order to give more decisionmaking power to the counties in mountainous areas in tackling the grain problem, so as to facilitate the readjustment of the agricultural structure, it is decided that the responsibility system of controlling grain within a specified quantity will be put into effect in the big counties in mountainous areas (not including those in the three autonomous prefectures). On the basis of current differences in grain purchasing and marketing in the areas concerned, some of these counties will be required to turn over grain by quotas to higher authorities, some can be provided with grain subsidies by quotas, while others will be required to realize grain self-sufficiency. The corresponding financial responsibility system will also be exercised in these counties. This measure will be maintained for the next 5 years.

The counties in mountainous areas where financial deficits could not be removed for many years running are now required to try out the financial subsidy responsibility system. Under this system, a fixed amount of subsidy which is equal to the deficit in the 1982 budget will be allocated to a county concerned in each of the next 3 years. Henceforth, financial surplus there can be controlled by the counties and should mainly be used for developing the economy in mountainous areas, highway construction, cultural and educational undertakings and the popularization of science and technology. After this responsibility system is put into effect, new items laid down by higher authorities which give rise to increases in expenditure or reduction in income should all be undertaken by these counties except the salary adjustment in administrative institutions which will be borne by the provincial authorities. The provincial authorities will put the above principle into effect in Peiling, Wanxian and Yaan Prefectures where financial expenditure exceeds income. These prefectural authorities can decide specific methods to exercise the financial responsibility system in their counties. As for other deficit-incurring counties in mountainous areas, financial responsibility system quotas will be laid down by the prefectural authorities. The province will maintain the current financial system between the province and these prefectures. But the province will exclude the financial surplus in the counties where financial responsibility system is in effect when it workd out financial targets for these prefectures.

7. Agricultural and sideline products will be purchased on the basis of quotas or proportions. The policy in this aspect must be stable. The contract system should be earnestly perfected. Targets laid down by the state for unified purchase, assigned purchase and transfer of agricultural and sideline products

must be fulfilled. The right of the collectives and the peasants to dispose of the portion of products specified in the policy should also be guaranteed. In this aspect, the specific stipulations laid down by the provincial party committee and the provincial government.

8. For speeding up rural economic development, it is necessary to carry out various forms of integrated and joint undertakings. Under the principles of voluntary participation, mutual benefit, equality and consulation, joint-ventures and integrated undertakings in various forms between different regions and trades and between economic units under differnet ownership forms should be encouraged and developed. The units participating in joint ventures and integrated undertakings will maintain their ownership forms, subordinate relationships, their position as basic accounting units and the relationships in payment of taxes and transfer of profits. Their output value and taxes imposed on them will be calculated on the basis of basic accounting units. Party committees, governments and the departments concerned at all levels should strengthen planned guidance of integrated enterprises in various forms, prevent duplication in guilding factories and help them coordinate all aspects of the relationships in the distribution of economic interests. By organizing integrated undertakings and taking other forms to carry out economic and technical cooperation, planning councils, economic councils and the state-owned enterprises concerned at all levels should help counties in mountainous areas and minority nationality regions develop the processing industry and mining industry and handle primary processing and multipurpose use of products. The experience of Qionglai, Dazhu, Hechuan and Gulin Counties in handling integrated undertakings should be summed up and promoted. At the same time, it is necessary to energetically develop various special households, key households and associated households in rural areas, support peasants' household sideline occupations and encourage peasants to get rich by working hard.

9. In order to train various types of technical personnel with professional knowledge for rural construction, it is necessary to step up the reform of the secondary education system in rural areas. It is required that most of the counties should transform one of the existing ordinary secondary schools into a vocational secondary school (not responsible for assigning work to students after graduation) within 2-3 years. At the same time, vocational classes should be run in ordinary high schools and professional courses should be offered there. Vocational schools transformed from ordinary schools will receive their funds through the former channels and be managed unifiedly by the educational department and they will be provided with more professional teachers. The departments concerned should organize some professional technicians to work as part-time teachers in these vocational schools. They should also offer their support by providing training places and requisite experiment equipment. All professional departments can run various short-term technical training classes according to needs.

10. In order to replenish and strengthen the cadre ranks at the commune level, besides following the three measures put forth by the provincial party committee earlier this year, vacancies in the commune leading organs can be filled by selecting some capable personnel from the commune cadres still engaged in production on a part-time basis and from excellent cadres of brigades and teams

with party membership. They should be young and strong, have good educational and technical backgrounds and pass strict tests. (The three measures put forth by the provincial party committee earlier this year are as follows: 1. Selecting some technical secondary schools graduates in agronomy, forestry, hydraulic engineering and finance every year and assign them work in the commune organs. 2. From the personnel who fill the staff quotas left by retiring cadres, selecting those who are promising and meet the requirements for cadres to work in the commune organs after giving them overall tests. They will still be treated as workers and continue to be temepred and tested in the first 2 years, and after that, those who are outstanding can be promoted as commune cadres. 3. From enterprises, institutions and administrative organs, selecting some of the excellent agricultural technical personnel and young cadres to strengthen the commune cadre ranks.)

At the end, the document said: If something in the documents issued by the provincial party committee and the provincial government in the past does not conform with the stipulations in this document, the norms for future work should be the regulations in this document. Party committees and governments at all levels and the provincial departments concerned should work out specific measures and methods in accordance with the above regulations and guarantee their implementation.

BRIEFS

PIGS--By the end of June, Sichuan had 51 million pigs, 920,000 more than at the beginning of the year. The trend for the number of sows to decline has been reversed, since there were 3.36 million at the end of June, 110,000 more than in January. During the first half of the year 12.32 million porkers were marketed, 230,000 more than in the same period last year. [Chengdu Sichuan Provincial Service in Mandarin 0030 GMT 28 Jul 82 HK]

CSO: 4007/511

BRIEFS

SUMMER-AUTUMN CROPS--The serious drought has resulted in the reduction of summer crop output in Taianjin. To make up the reduction with the increase in autumn crops, Tinajin has expanded the acreage sown in coarse food grain by 150,000 mu and the acreage sown in high-yield corn by 430,000 mu. Among the 680,000 mu of cornfields in Wuquing County, 90 percent are of fine strains. Thanks to the fainfall on 12 June, the drought in most areas has been relieved, but some areas still suffer from drought. [SK220433 Tianjin City Service in Mandarin 0030 GMT 22 Jul 82]

BRIEFS

HOG PROCUREMENT--As of the end of June, 5,539,700 hogs had been purchased from Zhejiang Province, fulfilling 58.3 percent of the annual procurement plan and topping the record for last year's corresponding period by 26,000 head. During the first half of this year, 3.86 million hogs were butchered for the province's meat market. [Hangzhou Zhejiang Ribao in Chinese 13 Jul 82 p 1 OW]

TITLE: "Breeding of Upland Rice Varieties by Means of Irradiation"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 1, 1982 pp 15-21

TEXT OF ENGLISH ABSTRACT: Red-grain rice varieties are popularly grown in Fengxin County. They have good adaptability and are tolerant of cold weather. Some varieties, such as Liu-tiao-hong, have very good palatable qualities. But these varieties usually have been tall and lodged easily, hence lower in yield. Since 1973 we have begun to improve these upland rice varieties by means of irradiation. So far 14 mutant lines have been obtained, among which 4 mutant lines seem to be very promising.

TITLE: "Inquiries Into the Technical Measures of Soybean Production in Heilongjiang Province"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese Nc 6, 17 Jun 82 pp 6-7

ABSTRACT: While soybean is not as adaptable as other crops, it also changes easily into a variety of forms under all different conditions. Although in China, aside from some high and cold areas of Qinghai-Xizang Plateau, soybean is cultivated everywhere, judging from the natural, economic, and social conditions, Heilongjiang is the most favorable for large acreage commerical production of soybean. The unit yield has been only 130-160 jin/mu for many years, however. The problems are as follows: (1) Regionally soybean does not react to nitrogen fertilizer as favorably as corn, wheat, rice, etc. The application of fast acting phosphorus fertilizer is the solution. (2) Incomplete germination of seeds due to extensive cultivation and poor soil moisture: The problem may be overcome by seeding later, using early maturing breeds, and using herbicides for more effective weed control. (3) The problem of drought and flood due to uneven distribution of rainfall may be helped by using small-seed varieties and irrigation. (4) The northernmost area of Heilongjiang is not

[continuation of NONGYE KEJI TONGXUN No 6, 1982 pp 6-7]

suitable for soybean, neither is the western saline and alkaline lands, but this problem may also be overcome if suitable breeds are selected. (6) The acreage of soybean is expanding and the condition of water and fertilizer is improving in Heilongjiang recently but soybean diseases are also becoming more serious. Sunflower encourages the spread of sclerotinia rot; therefore, whereever soybean is the major crop, sunflower acreage should be small and scattered. This is especially essential in low and damp regions.

TITLE: "Prospect of Wheat Development in South China"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 6, 17 Jun 82 pp 8-9

ABSTRACT: The 3 provinces and 1 region of South China have 9 percent of the wheat acreage of China and 7.6 percent of the total wheat production. The unit yield of Guangxi is 64 jin/mu, Guangdong 49 jin, and Fujian 97 jin, mostly lower than the national average of 86 jin. Failure to improve the unit yield also causes the wheat acreage to fluctuate from year to year. Although this subtropical region has superior condition of water and heat, the crop repeating index is high and many crops are suitable for the winter. If the ratio of wheat acreage is to be enlarged to raise the living standard of the people, ways must be found to increase the unit yield. The major problems include diseases, proper fertilizer application, and breeding locally suitable high yield variaties. The paper maintains that it is not true that there is no future for wheat development in South China. The key is research to improve the level of scientific cultivation of wheat. There is a great potential in improving the unit yield of wheat in South China.

TITLE: "Genetic Effects of Radiation on Rice Hybrids"

SOURCE: Fuzhou FUJIAN NONGSUEYUAN XUEBAO [JOURNAL OF THE FUJIAN ACADEMY OF AGRICULTURAL SCIENCES] in Chinese No 1, 1982 pp 25-28

TEXT OF ENGLISH ABSTRACT: The F_1 generations (M_1F_1) of different hybrid combinations in rice were radiated by Co rays of 30 kr. The radiation caused genetic effects on the different quantitative characteristics in the M_2F_2 generations.

Induced effects of the different quantitative characteristics were shown in the following two aspects:
1. Though the magnitude of mean population values of irradiated populations were not significantly different from that of unirradiated populations for most of the quantitative characteristics, the population coefficients of variation were increased and the heritabilities were also strengthened.
2. Some of the mean values of irradiation populations were significantly different from those of the control populations for quantitative characteristics and appeared to have positive effects (favorable mutation effects) or negative effects (unfavorable mutation effects).

[Continuation of FUJIAN NONGSUEYUAN XUEBAO No 1, 1982 pp 25-28]

The magnitude of induced effects of production characteristics was estimated with coefficients of variation and hereditability in the M_2F_2 generation and it is taken by the following order: number of effective ears → number of grains → percentage of seeds set → 100 grain weight.

TITLE: "Identification of Strains of Soybean Mosaic Virus"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 1, 1982 pp 15-20

TEXT OF ENGLISH ABSTRACT: The symptomatology, physical properties, host range, transmission and varietal reaction of six isolates of soybean virus collected from Jiangsu and Heilongjiang were studied. All of them could produce local lesions on the index plant, Phaseolus vulgaris L. "top crop," and could be transmitted by the peach aphid (Myzus persicae Sulzer), radish aphid (Lipaphis eryzimi Kattenback), and alfalfa aphid (Aphis craccivoro Koch). In soybean sap, their properties were thermal inactivation between 50~55°C or 55~60°C dilution end point between 10^{-2}~10^{-3}, longevity at room temperature (>25°C) between 24~36 hr. Electron microscopy of leaf dip preparations from soybean leaves stained negatively with PTA revealed flexuous particles. They had a narrow host range and only infected a few species of Leguminoceae. However, varietal reactions on soybean cultivars were significantly

[Continuation of ZHIWU BAOHU XUEBAO No 1, 1982 pp 15-20]

and consistently different. On this basis, they could be identified as six different strains of soybean mosaic virus (SMV). When the same strain was inoculated on different cultivars of soybean in a greenhouse, the symptom expressions differed obviously. Hence, the designation of isolates based on symptom expressions seems unreliable.

TITLE: "Study of the Control of Leaf Rust of Wheat by RH-124 (4-n-Butyl-1, 2, 4-Triazole)"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 1, 1982 pp 21-26

TEXT OF ENGLISH ABSTRACT: The results of greenhouse and field experiments showed that RH-124 gave excellent control against wheat leaf rust.

The winter wheat seeds treated with RH-124 at the rate of 0.03-0.035 percent by weight could avoid the harm of leaf rust before winter. In spring, when most wheat plants raised their flag leaves and started to display the leaf rust, only one spraying with 750 g per ha. of this fungicide gave more than 90 percent control. Soil application with RH-124 by irrigation also produced satisfactory results.

TITLE: "Studies on the Resistance of Rice Varieties to Viruses"

SOURCE: Fuzhou FUJIAN NONGXUE YUAN XUEBAO [JOURNAL OF THE FUJIAN ACADEMY OF AGRICULTURAL SCIENCE] in Chinese No 2, 1982 pp 15-18

TEXT OF ENGLISH ABSTRACT: The present report deals with the determination of the resistance of rice varieties to RTYV (RYSV), RDV, RBSV and RRSV.

1. Among the 219 varieties tested during 1973-1975, none of the tested varieties was immune to RTYV and RDV.

More than 15 varieties were considered to be highly resistant to RTYV, including Chikuaiai 3, 691, Tadukan, Longge 1 and Longge 113, etc. Thirty-seven varieties were moderately resistant, such as Zhenlong 13 and Wanxian 1, etc. Seventy-nine varieties were moderately susceptible, such as Shaaida and Lucai, etc., while 88 varieties were highly susceptible, including Zhenzuai 11 and Short White Seeder, etc.

Thirty-four varieties were highly resistant of RDV, including Tetep, Chikuaiai 3, Guba 154 and Mudgo, etc.; and 39 varieties were moderately resistant, such as

[Continuation of FUJIAN NONGXUE YUAN XUEBAO No 2, 1982 pp 15-18]

Malaihong, Nongshi 4 and Zhenlong 13, etc. Fifty-one varieties were moderately susceptible, such as Zhenshan 97 and Chaiyeching 8, etc.; and 95 varieties were highly susceptible, including IR 24 and IR 24 x TN-1, etc.

2. Among the 16 varieties tested during 1978 and 1981, none of them was immune to RBSV. The highly resistant varieties were Chikuaiai 3 and Baotaiai; moderately resistant varieties were Cuba 154, Zhenlong 13, Zhenlong 410 and Nongshi 4; and moderately susceptible varieties were Longge 16, IR 24, V 41 and V 20, while the others were all highly susceptible.

3. Among the 32 varieties tested during 1980-1981, none of them was immune to RRSV. The highly resistant varieties were Chikuaiai 3, Shannung 3, Shannung 8 and Chikuaiai-Xiuan; the moderately resistant varieties were IR 30-Xiuan, Baotaiai, Fengaizao A x DT Ai; while moderately susceptible varieties were IR 2061-427-1-17-7-5, IR 29, IR 30 and IR 36, etc. The highly susceptible varieties were Puichao 2, IR 24, Siyou 4 and Shanyou 6.

TITLE: "Studies on the Root Development of Hybrid Rice"

SOURCE: Fuzhou FUJIAN NONGXUE YUAN XUEBAO [JOURNAL OF THE FUJIAN ACADEMY OF AGRICULTURAL SCIENCE] in Chinese No 2, 1982 pp 19-27

TEXT OF ENGLISH ABSTRACT: Hybrid rice plants (Oryza sativa L.), hybrids "San-you 2" and "Se-you 2" were used as testing materials, and cultivars "Hong-410," "Da-jia-huo" and "San-bang-70-luo" were used as controls in this study. They were grown both in pots and field plots in 1978-1980. Treatments were carried out during the periods of the 2, 4, 6, 8, 10, 12, 14 and 16 leaf stages, milk stage, dough stage and maturation stage. At each stage the formation of superficial roots, bleeding sap of stem, volume and dry weight of the roots and potency of rooting, etc., were measured. The results obtained are briefly described as follows:

1. The diameter, volume and dry weight of the roots (the density of superficial roots) of the hybrids "San-you 2" and "Se-you 2" were larger than those of the rice cultivars "Hong 410" and "Da-jia-huo," but the diameter and dry weight of the roots were less than those of the cultivar "San-bang-70-luo" with respect to the formation of lateral roots. Visual observations showed that "San-you 2," "Se-you 2" and "San-bang-70-luo" branched up to the fifth order, while "Hong-410" and "Sai-zai-ho" branched up only to the tertiary.

[Continuation of FUJIAN NONGXUE YUAN XUEBAO No 2, 1982 pp 19-27]

2. Both hybrids "San-you 2" and "Se-you 2" showed the maximum weight of roots, the maximum power of sap bleeding and the maximum potency of rooting during the dough stage, and 14 leaf-stage respectively. However, the maximum development of rooting per day was reached at about the time of the highest tillering activity. After that the climax of sap bleeding per day was reached, and at the same time an increase of tillers continued up to the greatest tiller development. Then some of the tillers died, making the total number of tillers smaller. The dry weight of roots increased up to the boot stage. However, sap bleeding per day occurred in the dough stage as the secondary summit.

3. When roots were cut at the 4, 6 and 8 leaf stages, the number of tillers was reduced with the decrease in the number of panicles. Kernels per panicle and filled grains decreased when the root was cut at the 12 leaf stage. Furthermore, the rate of filled grains was much less than that of the control when the roots were at the 16 leaf stage.

4. Roots of multiple tiller seedlings were better developed than those of multiple seedlings per hill.

Irrigated field plots with a water layer at the early growth stage and maintenance of wetness thereafter induced active growth of rice roots.

TITLE: "The Application of Remote Sensing Technology to Soil Surveys. II: MSS Image Interpretation of Soils Division in Jinjiang Region of Fujian Province"

SOURCE: Fuzhou FUJIAN NONGXUE YUAN XUEBAO [JOURNAL OF THE FUJIAN ACADEMY OF AGRICULTURAL SCIENCE] in Chinese No 2, 1982 pp 39-51

TEXT OF ENGLISH ABSTRACT: Jiajiang Region is situated on the southeastern coast of Fujian Province at the longitude between 117°30'-119°00' E, latitude 24°30'-25°55' N. It covers a space of over 10,000 sq km.

Jinjiang's climate is considered subtropical marine with seasonal wind. The mean annual temperature is about 20°C, and the mean annual precipitation is about 1,200 mm. From May to November, known as the typhoon season, the rain is accompanied by violent whirlwinds, and this accounts for 30 percent of the total rainfall. From October to January is the dry season. The landform elevation is higher in the northwest and lower in the southeast. The hills and plains are distributed in the southeast. They belong to the Quanzhou plain and the Jinjiang-Huian hill region, and are the base of food and economic crop production.

[Continuation of FUJIAN NONGXUE YUAN XUEBAO No 2, 1982 pp 39-51]

In accordance with the MSS image interpretation of soils, air photograph and actual ground investigation of the soils, the soil associations distributed in the types of various landforms are as follows:

Type of landform	Soil associations		
	dominant (50%)	associated (20-50%)	inclusions (20%)
A. Quanzhou seashore plain			
1. deltaic plain	W_1-3a	S-3a	
2. old deltaic plain	L_t-3b	W_1-3a	W_g-3a
3. rock depositional plain	S_{ba}-3a	S_{ti}-3a	
4. tide island lowland	A_{se}-1a		
5. sea terrace (shallow dissected-platform)	L_t-3b	L_{fe}-3b	W_p-3a
B. Hill (300-500 m)			
1. lost hill of old island	L_{fe}-1b	R_o-1b	
2. rocky hill	R_o-1b	L_t-1b	

[Continuation of FUJIAN NONGXUE YUAN XUEBAO No 2, 1982 pp 39-51]

C. Low mountain (500-1000 M)			
1. mid-dissected	R_t-3c	R_y-3c	W_g-3a
2. shallow dissected	R_t-3b	W_g-3a	W_1-3a
3. valley basin	W_1-1a	R_t-2b	
D. Midmountain (>1000 M)			
1. strong dissected	Y_m-1c		P_m-1a
2. mid-dissected	Y_m-2c	W_g-2a	
3. shallow dissected	Y_m-2b		W_p-1b

TITLE: "On the Classification of Rice Growing Region of Fujian Province"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 3, 10 Jun 82 pp 13-16, 23

ABSTRACT: Fujian Province is obviously divided latitudinally, longitudinally, and vertically. The rice cropping systems and the rice breeds vary a great deal from area to area within the province. This paper explains that a rice cropping area is composed of natural as well as social factors, with heat energy the leading factor. On the basis of mainly the data of the Fujian Provincial Bureau of Meteorology, the paper divided the rice growing region of the province into the following areas: (1) The dual crop late ripening Xian rice area of the southern plain and hills; (2) The medium and early ripening continuous cropping Xian rice area of the central plain and hills; (3) The dual crop medium ripening Xian rice area of the northwestern and northeastern hills; (4) The single and dual crop early and medium ripening Xian and Geng rice area of the northwestern low mountains; (5) The single crop rice area of the high mountains. Breeds of the proper ripening time, the suitable seeding and transplanting time, and the cropping system should be decided upon only after a locality is correctly assigned to one of the above rice growing areas if the yield is to be high and stable.

TITLE: "China's Traditional Methods of Seed Treatment"

SOURCE: Beijing ZHIWU ZAZHI [JOURNAL OF BOTANY] in Chinese No 3, May 82 pp 35-37

ABSTRACT: Seed treatment to promote germination and growth, to reduce damage from diseases and pests, to induce early maturity, or to cause favorable mutation is a modern, scientific, and common technique but many seed treatment measures being applied in present day China, including sunning, soaking in cold water or warm liquid mixture, variable temperature treatment, mixing seeds with chemicals, soaking with trace elements or growth stimulating agents, vernalization, and ultrasonic wave and radiation treatment are in fact developed on a foundation of China's traditional techniques. Methods of mixing seeds with animal manure and/or herbal drugs, sunning and/or soaking seeds, stratification treatment in sand or a pit, mechanical rubbing, and mixing seeds with herbal pesticides described in old Chinese literatures from as early as the Zhou Dynasty to as recent as the Ming Dynasty are briefly introduced in the paper.

EXHORTATION FOR RURAL ECONOMIC DIVERSIFICATION ISSUED

Shijiazhuang HEBEI RIBAO in Chinese 15 Jun 82 p 1

[Article: "New Prospects Must Be Opened For Rural Economic Diversification"]

[Text] Not long ago when Comrade Hu Yaobang made an inspection of Baoding Prefecture in Hebei Province, he noted that "Two changes have to be made in agriculture, the first of which is a change from sole attention to grain to simultaneous attention to economic diversification, and the second of which is a change from sole building of water conservancy to simultaneous attention to water and soil conservation and improving soil cover." This important instruction from Comrade Hu Yaobang is a scientific distillation of agricultural development since founding of the People's Republic. It possesses major significance for accelerated agricultural development and the flourishing of the rural economy so that the peasants can become prosperous with all possible speed. We must conscientiously put into practice Comrade Hu Yaobang's major instruction, opening new prospects for the province's economic diversification.

Since the Third Plenary Session of the 11th Party Central Committee, as a result of thoroughgoing criticism of "leftism," readjustment of agricultural crop patterns, and implementation of the party's various rural economic policies, the province's economic diversification has seen very great growth in the farming industry, in the aquatic breeding industry, in processing industries, and in industrial sideline occupations. The broad masses of peasants have increased earnings, the rural economy has become lively, city and countryside markets flourish, and the rural situation is very encouraging. However, it must be realized that the province's development of economic diversification is merely in an incipient stage, and is a long way from meeting the demands of higher authority or developing to the extent to which it can develop. First of all, the guiding mentality at all levels in the province has yet to change completely from sole attention to grain to simultaneous attention to economic diversification, and economic diversification has not yet been elevated to the important position it should occupy. Second, following institution of systems of responsibility for production, a large portion of surplus rural labor has not yet been properly provided for. Third, in mountain regions, the plains, and on water surfaces alike, the potential for economic diversification is still a long way from being tapped. So one might say that economic diversification has not been far off the mark; it has been a long distance from the mark. The major task for all levels of leaders at the present time is to rapidly effect a genuine change in the guiding mentality from sole attention to grain to simultaneous attention to economic diversification, with good planning and strengthening of leadership so that economic diversification in the province will have greater development from its existing base.

If there is to be a change from sole attention to grain to simultaneous attention to economic diversification to open new prospects for economic diversification, horizons will have to be broadened and avenues opened, the collective and individuals rising together, and staples and non staples being given attention together. The province's resources are fairly bountiful. We should not only look at the 10 to 20 percent of mountainlands. On the plains, we should not only look at the limited amount of cultivated land, but look even more at the large quantity of idle wastelands and water surfaces. We should not only look at the output value and earnings from single production, but should look even more at the increased output value and greater earnings from multiple processing. In a word, our horizons have to be expanded to the vast world. In terms of the province as a whole, full use should be made of skilled craftsmen to teach apprentices to serve a role in the transfer of skills. A campaign should be organized for skilled people to teach large numbers of people and for large numbers of people to learn from skilled persons to transfer the large quantities of surplus workforces into economic diversification to engage in the trades and industries of farming, raising of aquatic products, processing industries, and service trades so that each person is used to the full extent of his abilities. Second is full development for use of the province's more than 62 million mu of barren mountains and wasteland slopes, its more than 2.9 million mu of desert wastes and saline-alkaline land, its more than 1.2 million mu of fresh water surfaces and 860,000 mu of coastal shallows, and all resources that have not yet found use or have not yet found full use so that the land will be used to the full extent of its strength. Third is efforts to develop brand name goods, commodities in seriously short supply, agricultural and sideline product processing, and service trades for large and medium size cities and small cities and towns. Where conditions permit, efforts should be made for multiple increases in output value. Things that can be used should be used to their fullest extent. Fourth is that while continuing to give attention to centralized collective administration, sideline occupations that lend themselves to being done by commune member households should be handled by individual commune member households for vigorous development of household sideline occupations. Production brigades and production teams should adapt general methods to individual households to help in the formulation of plans, deciding on things to be done, teaching skills, finding markets, and in formulating specific regulations helpful to development of household sideline occupations. This is one important aspect of the widening of avenues of economic diversification. Fifth is attention to good selection of breakthrough points. Broadly speaking, we want all around development of economic diversification. However, in terms of an individual county, an individual commune, or an individual production brigade, attention should be directed to one or several local things that can be readily handled, use made of focal points to spur on the whole.

Yet another important issue in active development of economic diversification is the need to correctly handle the relationship between grain production and economic diversification, with no relaxation of grain production under any circumstances. The experiences of history have told us that only when increases in grain production are assured is it possible to lay a firm foundation for development of economic diversification, and that growth of economic diversification can, in turn, provide more advantageous conditions for increased production of grain. We definitely must fully understand this dialectic relationship; we must not use a decrease in grain to increase economic diversification, but rather should blaze a new trail that both assures year by year increases in grain output and that can also greatly increase economic diversification to achieve a takeoff in both grain and economic diversification.

The establishment and perfection of various forms of responsibility systems is a key in arousing the enthusiasm for economic diversification of commune members. The practice during the past several years of various forms of agricultural responsibility systems has universally aroused the serious attention of the entire party and has achieved very good results. However, systems of responsibility in commune and brigade industrial sideline occupations have lagged behind agriculture. Henceforth, while perfecting and improving agricultural responsibility systems, all jurisdictions should devote major efforts to economic diversification responsibility systems, contracting to specialized teams, specialized units, and specialized households economic diversification tasks. It should be noted here that in commune and brigade enterprise contracting, it is necessary to adhere to the collective nature with most benefits reverting to the collective. There can be no nominal contracting that is converted in reality to small number of people having ownership. Wherever a small number of people have taken possession in the past, collective operations must be resolutely revived and thereafter a suitable economic responsibility system should be built and perfected by proceeding from a strong and solid collective economy. In the development of sideline occupations, there should be vigorous development of specialized households and of all kinds of collective groups; not only should operations by combinations of households be advocated, but even broad combinations that transcend commune and brigade lines should be allowed to develop.

The areas on which economic diversification bear are very broad, and under the centralized direction of the party, all units in all jurisdictions should work together to give vigorous support and assistance to communes, brigades, and the broad masses of commune members in every way. All levels of CCP committees and governments and related units should gunuinely strengthen concrete leadership, help communes and brigades institute the "two changes," and further formulate plans for development of economic diversification. They should conscientiously put into effect the principles of taking the planned economy as the key link in agriculture with market regulation playing a supplementary role." They should indoctrinate the broad masses of cadres and commune members in concurrent concern for the interests of the country, the collective and individuals, to link present interests and long range interests, to do centralized planning, to have all around development, to enliven the economy, and to increase effectiveness. They should teach cadres and commune members to adhere to a socialist orientation and to take the road of getting rich through labor, to not contravene national policies and laws, and to strike down evil influences on the country and the people so as to have healthy development of economic diversification.

In the process of developing economic diversification, scientific and technical knowledge should be spread for the gradual formation of a huge mass science and technology corps. It is necessary, first of all, to adopt advanced techniques for use, to promote fine varieties, and to prevent and control diseases and insect pests, to create name brands through economic diversification, to insure quality, increase confidence, and meet the needs of society. State owned and collective commercial units should do a good job of market forecasting, and provide commodity information, to help the peasants arrange production in a rational way and prevent large ups and downs. In addition it is necessary to open flow channels, to open markets at home and abroad for the products of economic diversification, and strive to decide production on the basis of the market so that goods flow freely.

We believe that if only the people of the province rally their spirits, emancipate their mentalities, play up strengths and play down weaknesses, make the most of advantages, each trade and industry striving together, rural economic diversification in the province is bound to be able to rapidly open new prospects.

NOTICE ON PREVENTION OF COTTON DISEASES PUBLISHED

Shijiazhuang HEBEI RIBAO in Chinese 13 Jun 82 p 1

[Article: Hebei Provincial People's Government Notice On Conscientious Launching of Survey Work on Verticillium and Fusarium Wilt of Cotton"]

[Text] (Not Otherwise Circulated)

Government Administrative Offices in All Prefectures:

In order to prevent the spread of damage caused by cotton verticillium and fusarium wilt disease, all prefectures are to conscientiously inspect the occurrence of disease damage during the period of cotton growth.

1. Leadership comrades concerned in all prefectures and countries are to act personally to organize personnel in agricultural, supply and marketing, and cotton buying units to give active attention to this work. They are to do a good job of propaganda education and technical training to arouse the masses to engage in the survey.

2. The survey is to be carried out at two different times, the first time being the cotton's early budding stage (in June) and the second time being the boll stage (in August). The area of disease occurence and the extent of disease occurence are to be carefully checked, and areas of heavy incidence, light incidence, patchy incidence, and on incidence delineated. Survey results are to be promptly reported to the Provincial Department of Agriculture.

3. The survey is to serve as the basis for planning all around prevention and control. Areas of heavy incidence are to be clearly recorded so that next year reverse cropping or planting of resistant varieties can be done. In areas of light incidence or patchy incidence, diseased plants should be dug up at once and the soil disinfected. In disease-free areas, good protection work should be done, disease-free fine varieties bred, a strict quarantine system instituted, and the spread of diseased seeds and bacteria-carrying beancake fertilizer to disease-free areas controlled.

HEILONGJIANG

BRIEFS

SUBTERRANEAN RIVER DISCOVERED--Heilongjiang Province has discovered for the first time a subterranean river. This was recently identified factually after several years of survey and prospecting by provincial metallurgical and geological workers. The subterranean river, located in the Xiling District of the city of Yichun, measures 3 kilometers in total length. The source of the river is located about 50 meters underground, with its river outlet meeting the southern river bank of the small Xilin river valley. This subterranean river is rich in griotte, and has a complicated geologic structure. The area close to the river has dense forest, flourishing terrene water systems, and sufficient rainfall. During the dry season, the rainfall has a daily flow capacity of 9,000 cubic meters, and reaches more than 40,000 cubic meters daily during the wet season. The departments concerned have determined that this subterranean river has water of superior quality and reliable flow capacity, making it an ideal water source for industrial and civil use. Furthermore, the river is near Xilin Steel Mill. This has a rather important economic significance to the tight water supply situation that the steel mill faces. DEVELOPMENT OF HOG-RAISING INDUSTRY NOTED

Beijing RENMIN RIBAO in Chinese 4 Jul 82 p 2

[Text] The hog-raising industry continues to develop in Siping Prefecture, Jilin Province. As of the end of the first quarter of this year, the prefecture's live hog population totaled somewhat more than 1.36 million head, a 4.38 percent increase over the same period last year. Three hundred thousand head were removed from inventory, a 9.24 percent increase over the same period last year. This included 54,800 head sold to the state, a 6.53 percent increase over the same period last year.

Siping Prefecture is an advanced area for hog-raising in Jilin Province. This year live hog production has continued to develop throughout the prefecture, mostly through reliance on policies to arouse the enthusiasm of the peasants for raising hogs, and reliance on science to improve hog-raising techniques. This year the prefecture universally established and perfected various kinds of hog-raising production responsibility systems. Some counties also enacted bonus systems for raising hogs. Lishu County, for example, stipulated that the countywould give a bonus of 200 yuan to any commune that raised one hog per person. If the commune sold one commodity hog per household, the county would give the commune a 300 yuan bonus. In this way, it aroused the enthusiasm of both the collective and of individuals for raising hogs.

In order to give real help to hog-raising households in solving problems of obtaining livestock feed; acting in accordance with regulations, the entire prefecture apportioned an overwhelming majority of the animal fodder raising land to hog-raising households. Some production teams also farmed a certain amount of collectively own feed producing land or took over some reserve livestock grain for use in preparing feed for developing live hog production during the current year. By way of encouraging commune members to raise more hogs, Siping City stipulated that for every boar or sow raised by vegetable growing peasants in the suburbs, in addition to the 250 jin of concentrated feed provided by production teams, an additional 200 jin of mixed feeds would be provided. For every live hog raised by peasants growing nothing but vegetables and to whom no land had been apportioned for the growing of livestock feed, 500 jin of mixed feed would be provided.

A full supply of hog sources is one of the major requirements for development of the hog-raising industry. Siping Prefecture conscientiously took in hand the job of state farm and collective raising of boars and sows. The prefecture has 6 state hog-raising farms, which so far this year have bred 1,400 stud hogs, which have been sold to communes, brigades, specialized households, and key households for raising. Quite a few communes and brigades have given attention to the consolidation and development of collective hog-raising. As a result of having done a good job in collective hog-raising, in having solved its problems with sources of hogs, in having stabilized shoat prices, and in having raised one hog per person for many years in a row, Shuangyushu Commune in Huaide County made another breakthrough this year. Statistics as of the end of April show the number of live hogs in the commune being fed as 15,500 head, or 0.7 head per person, placing it in first place in the prefecture.

This prefecture has also vigorously promoted scientific techniques for raising pigs, and has bolstered epidemic prevention and disease eradication work. The Prefecture Main Veterinary Station ran a pilot project at Taiping Commune in Lishu County on cooperative prevention and treatment of livestock diseases and the insuring of hogs. The specific method used was for the veterinary station to contract with hog-raising households for epidemic prevention, medical treatment, and cost of hogs (guaranteeing 25 yuan for each hog that died). The hog-raising household paid an annual insurance premium of 2 yuan per hog. Results of the project shows that this method is simple, convenient and workable; veterinarians were satisfied and the masses were delighted. During this year, the method has been promoted and put into effect everywhere throughout the prefecture.

In order to solve problems of "difficulty in selling hogs," in early February this year, commercial units at all levels signed assigned hog-raising and assigned purchase agreements with hog-raising households. The plan's assigned quota for the prefecture was 2.14 million head and the assigned procurement quota was 460,000 head. Agreements were signed on this basis. If hog-raising households did not sell their hogs at the time stipulated in the agreement, for each days delay in selling, they had to pay a 0.10 yuan damages fee to the commercial unit. For each day the commercial unit was late in accepting delivery, it had to give the hog-raising household a fee subsidy fee of 0.30 yuan per head per day. Everybody called this agreement "double insurance," and it made hog-raising households feel as though they had swallowed "tranquilizers."

MEASURES TO FIGHT BACTERIAL BLIGHT OF RICE DISCUSSED

Xian SHAANXI RIBAO in Chinese 11 Apr 82 p 2

[Article: "Remarkable Success in Prevention and Control of Bacterial Blight of Rice in Hanzhong Prefecture. Production Area Quarantine and Prevention and Control of the Spread of Diseases and Insect Pest Begun"]

[Text] Plant protection and plant quarantine station science and technology personnel in Hanzhong Prefecture have won striking successes in the prevention and control of paddy rice bacterial blight over large areas.

Beginning in 1980, this plant protection and plant quarantine station set up 655 disease-free bases on more than 350 mu area. Thanks to the painstaking care of technical farm cadres and the masses, 1.68 million jin of blight-free first generation hybrid rice seeds were harvested in the fall of the same year, and more than 17,900 jin of "three lines" rice seeds plus 700,000 jin of conventional rice seeds free of blight were also harvested. These disease-free seeds were planted for open field production in 1981. The diseased field area dropped strikingly, and the extent of damage decreased greatly. Survey statistics show that as a result of the spread throughout the prefecture's producing areas of the single measure of quarantine to prevent the spread of disease damage, 6.05 million jin of paddy was saved in the same year. After summarizing experiences, in 1981 they formulated "Trial Regulations for Hanzhong Prefecture Paddy Rice Seed Producing Area Quarantine," while enlarging to 17,575 mu the disease-free paddy rice base area so as to lay a foundation for further eradication this year of bacterial blight.

The specific methods they used were as follows: (1) Effective inspection to understand the disease situation. During the fall of 1979 8,300 quarantine inspectors were training throughout the prefecture, and 434 communes carried out field inspections so as to clearly delineate the dividing line between disease and disease-free zones as data for formulating prevention and control measures. (2) Adoption of multiple measures for the breeding of disease-free seeds. In establishing disease-free fine variety breeding bases, they followed quarantine requirements, using "dikushuang" to soak the chosen rice seeds prior to planting them. In propagating seedlings and caring for them in open fields, strict attention was given to proper watering, fertilization, and use of pesticides to prevent outbreaks of bacterial blight. (3) Implementation of quarantine in producing areas and promotion of disease-free seeds for sale. Before the rice was harvested, quarantine personnel from plant protection units and science and technology personnel from fine variety breeding units conducted joint quarantines of producing areas. In production teams where no bacterial blight had occurred, quarantine requirement certificates were signed and issued in the fields and procurement contracts signed on the basis of the area involved. Following harvest of the rice, seed units became responsible for procurement, storage, and looking after the seeds. Before growing seedlings in the following year, disease-free seeds were taken, according to disease prevention plans, to disease-free areas or to communes and brigades lacking seeds in diseased areas where they were planted to put an end to the source of disease bacteria.

SCIENTIFIC FARMING PRACTICES DEMONSTRATED OVER WIDE AREAS

Xian SHAANXI RIBAO in Chinese 9 Apr 82 p 1

[Article by Xinhua She Correspondent Zhao Zhixiang [6392 1807 4382] and Xinhua She Reporter Dai Guoqiang [2071 0948 1730]: "Cadres Effectively Farm Model Fields to Promote New Agricultural Techniques. Yan'an and Yulin Prefectures Use Representative Demonstrations to Guide Scientific Farming"]

[Text] Beginning with this year's spring farming preparations, prefecture county, and commune party and government cadres, and scientific and technical personnel in Yan'an and Yulin prefectures in Shaanxi Province will farm model fields in concert with the peasant masses, using the method of representative demonstrations to promote new agricultural techniques and provide instruction in scientific farming. Right now the model fields in these two prefectures cover 200,000 mu.

Just before and after the lunar new year, Yan'an and Yulin prefectures convened conferences of cadres and commune member representatives to summarize experiences and analyze developments. It was generally acknowledged that in a situation in which agricultural production responsibility systems had already been universally established, it was necessary to give attention to the important link of scientific farming. To this end the leadership organizations of the two prefectures decided that beginning with this year's spring farming, cadres would farm model fields, adapting general methods to local situations to spread some effective advanced farming practices. These advanced farming practices were principally as follows: Farming using furrows in river plains areas; horizontal furrow farming on hillsides; and rotational cropping and intercropping of oil-bearing crops, beans, and grass on terraced fields and plains fields.

Before spring sowing began this year, Zhidan County transferred a group of leadership cadres and farm, forestry, and livestock raising technicians to form two work teams, which went to Xinghe Commune in Dongchuan and Jinding Commune in Xichuan to establish two model tracts for the planting of nearly 3,000 mu of model fields. They formed a link with and gave guidance to the eight "lead villages" farmed by the communes within the two tracts. These "lead villages" linked up in turn with the surrounding "scientific and technical households" to promote the aforestated advanced farming methods for spring sowing and the new techniques of earliest possible sowing, reasonably close planting, and fertilizing with a mixture of nitrogenous and phosphate fertilizer. In the planting of 135,700 mu of model fields to millet, soybeans, broom corn millet, oil bearing crops, paddy rice, and wheat prefecture, county and commune cadre in Yulin Prefecture set up prefecture-wide guidance fields and lead fields for the popularization of scientific farming.

For all model tracts and model sites as well as for contracting households within the tracts and sites, technical contracts linked to output were universally signed. Contracts were signed for category 1 model tracts and with contracting households within tracts in Yulin, Mizhi, Zhidan, Yan'an, Fu, and Ganquan counties (or municipalities), and contracts were signed by all communes at model sites and by contracting households. The contracts stipulated the new techniques, the new varieties, and the farming techniques that were to be promoted, with rewards being offered for overfulfillment, any reductions in output to be made up by commune and county promoting units. In addition, county and commune model tracts were responsible for teaching technical knowledge and for the training of technical mainstay cadres. Before spring sowing began, Yan'an and Yulin prefectures trained more than 30,000 enrollees as technical mainstay cadres.

Right now an upsurge has been sparked in spring plowing and production in northern Shaanxi. As of mid-March, plowing and harrowing of almost 300,000 mu has been substantially completed in Yan'an and Yulin prefectures, and most of the barnyard manure to be used as base fertilizer for the fields had been sent to the model fields. Statistics show that the superb quality barnyard manure made ready for spring sowing in the two prefectures amounts to more than 100 million dan, a 20 percent increase over last year.

PRACTICAL SCIENTIFIC FARMING EMPHASIZED

Jinan DAZHONG RIBAO in Chinese 17 Apr 82 p 1

[Article: "Linyi Prefecture Gives Positive Attention to Agricultural Science and Technology Work. Achievements Scored in Agricultural Research, Spread of Techniques, and Scientific and Technical Education"]

[Text] Linyi Prefecture has given positive attention to agricultural science and technology work to score quite a few achievements in recent years in agricultural research, the spread of techniques and scientific and technical education.

Statistics show 136 research achievements for the prefecture as a whole, including 26 of which were of fairly high level, had fairly great economic benefits, and were worth promoting. One example was a method for the prevention and control of peanut green wilt, which was effectively able to control disease damage and increase yields for an increase of about 50 jin per mu, all conditions being equal. Experiments with bumper yields from young Chinese chestnut trees have brought yields of more than 1,000 jin per mu from small areas in Fei County. Following changes for the better, many old trees that had formerly virtually stopped bearing are now universally producing fruit, yields raising from the former 5 or 6 jin to about 60 jin, or a maximum of more than 130 jin. The Cangshan County Agricultural Institute carefully selected fine varieties of garlic, planted it reasonably close, scientifically fertilized it, used plastic sheeting, and employed such new farming techniques for yields last year of 3,764.8 jin per mu of fresh garlic bulbs and 1,320 jin of garlic flowers and stems, more than 80 percent more than from fields in general.

In the field of the spread of techniques, as a result of the selection of techniques that could gradually be spread from key points to wide areas, economic results were also very remarkable. An example was tackling the problem with black sajong soil. As a result of small area experiments conducted by the Wangqiao Commune Agricultural Science Station, yields rose from 278 jin per mu in 1975 to 945 jin per mu. Now results have been spread to more than 100,000 jin throughout the county. Ying County's experiences in building quick growing, high output forests were also spread to Linyi, Tancheng, and Cangshan counties. Last year the entire prefecture established this quick growing, high yield method for more than 110,000 mu of forests, and this year the area is to increase to more than 200 mu. In order to meet the needs of the broad masses of peasants to study science and use science, throughout the prefecture after-hours technical education has been actively launched. Now a vocational school corps of 15,000 teachers has been established, and more than 500,000 people are engaged in study. Training is in the form of year-round classes, seasonal classes, short training classes, and technical lectures. Year-round techncial training classes follows a 3 or 4 year educational system. When the period of training has been completed, if test results meet requirements, a diploma is issued. Those with outstanding achievements are designated "peasant technicians."

Recently Linyi Prefecture held a conference for the exchange of scientific and technical experiences at which 153 advanced collectives and individuals who had made achievements in research and the spread of techniques were given awards and commendations.

STEPS TO INCREASE HOG PRODUCTION REPORTED

Beijing RENMIN RIBAO in Chinese 4 Jul 82 p 2

[Text] The Sichuan Provincial People's Government recently approved and sent forward the Provincial Animal Husbandry Bureau's report requiring all municipalities, zhous, and counties in the province firmly to take in hand the production of sows to increase the source of hogs.

Recently a sustained decline has occurred in the number of sows in inventory in some key commodity hog producing areas of Sichuan Province, and the problem of a shortage of sources of hogs is a fairly prominent one. In Chengdu Municipality and in Wenjiang, Neijiang, Jinyang, and Nanchong prefectures, the number of sows capable of reproducing decined during the first quarter of thsi year by 12.6 percent as compared with the same period last year. In some prefectures and counties, sows account for only between 4 and 5 percent of the total hog population. The shortage of sources of hogs has already produced bad effects on development of hog-raising, and unless urgent action is taken to solve this problem, it will adversely affect the province's total output of pork.

By way of increasing sources of hogs, this province's animal husbandry units have required that all jurisdictions, first of all, raise the sows they already have, increase the shoat production rate, and aim for an average one more birth and one less death of shoats per sow per year. In this way it will be possible to increase the number of shoats produced by the equivalent of 600,000 head of sows and rapidly increase the number of sows in inventory. The number of sows in inventory throughout the province should not be less than 7 percent of the total hog population. On the basis of requirements all jurisdictions should adapt general methods to local situations to set a proper proportion of sows to be bred. Development of sow production requires bringing into play the initiative of both collectives and commune member households for raising sows, every effort being made to have production teams do the breeding and households do the raising, with further implementation of a bonus policy for the raising of sows. Production teams should annually set aside about 300 jin of feed grain per sow or else designate 1/10 or 2/10 mu of land for the raising of feed, make hog-raising a part of commune member contract agreements, take action to provide land for the growing of fodder to feed sows, with the land being taken back by the collective if no sows are raised in a system whereby hogs and land are linked. When sows bear young, state regulations on award sales of grain for production of shoats should be honored. In addition to taking action to produce sows, attention should also be directed to the promotion of fine hog species so that hybrid hogs in the province will increase from this year's 20 percent to 25 percent of the hog population.

PROVINCE STRIVES TO INCREASE HOG PRODUCTION

Hangzhou ZHEIJIANG RIBAO 24 Jun 82 p 1

[Text] The hog production situation in Zhejinag Province has been heartening throughout the year. As of the end of May the number of live hogs in inventory totaled 12.69 million head for a faster recovery rate than last year. State procurement of live hog throughout the province during the previous 5 months was 4.4 million head, a 2.4 percent increase over the same period last year. Markets within the province have liberalized pork supplies, and in most municipalities and counties supplies are unlimited. This has been the result of all levels of government having strengthened leadership in hog-raising, of diligent implementation of policies for commune and brigade hog-raising, and active fulfillment of live hog assigned procurement quotas.

The once a year small peak period in hog purchases has arrived under conditions of a gradual resurgence of live hog production. In recent days, foodstuff stations have been busy with buying and busy with selling, and cold storage plants have been very busy with butchering. It has been estimated that during June and July quantities purchased will approach last year's levels, and quite a few hog raising households are concerned lest this year become one of "difficulty in selling hogs."

It should be realized that hog-raising in Zhejiang Province is rather good this year, but it has not yet reached an all-time high. In some cities and villages, pork supplies are somewhat short, and both export and light industry units have increased required amounts. So in terms of the year as a whole and over the long term, there is no hog glut, but rather a need for continued production. As far as the concentrated sales of hogs during the current small peak season are concerned, this results from a conflict between seasons and areas. Commercial units have investigated and studied and are fully prepared to meet this situation. Plans have been readied for each of the links of procurement, transportation, butchering, storage, and marketing. As compared with last year, conditions favoring solution to "difficulty in selling hogs" are numerous. One is that cold storage capacity has been greatly increased. In addition to the existing more than 27,000 tons storage capacity in the province, 4 large and medium-size cold storage lockers have been built. Two of them at Jinhua and Ningbo have formally gone into service, and before the end of June the one at Jiaxing will be ready to store meat. One cold storage locker at Hangzhou will be used following major repairs. The total amount of pork that can be stored will amount to about 400,000 live hogs. Small cold storage lockers in some places can also function as "reservoirs" for the overflow. Second is liberalization of pork supplies in cities and the countryside. In Hangzhou, Ningbo and seven prefectures, there is unrestricted supply. Accompanying an increase in meat consumption by people in cities and the countryside has been more skinning and rendering of fat, and more processing of meat products, which has brought about an increase in quantities marketed. Third has been an increase in export requirements and the amount of pork used by light industry. Of course, in view of differences between one area and another in the speed of development of live hog production, as well as differences in patterns of sales and operating conditions, the problem of "difficulty in selling hogs" positively cannot be taken lightly.

During the small peak period of live hog procurement, what can be done to prevent occurrence of a situation of "difficulty in selling hogs"?

1. Reliance on the Active Efforts of Staff and Workers of Units Dealing in Foodstuffs. As far as staff and workers of units dealing in foodstuffs are concerned, if they do a good job of live hog procurement during the small peak period they will have taken the initiative for the year as a whole. In purchasing live hogs the experiences of Dongyang and Yiwu Counties should be promoted for "viewing hogs from door to door, issuing certificates as meeting specifications, fixing times and fixing places, and appointments to make sales." In light of the concentrated offerings for sale, the number of network outlet points have to be increased, the number of times for purchase in a given period increased, and early and late purchases made so that the pigs to be purchased will be purchased. In order to buy more pigs, it is necessary to sell more pork. This year villages have had a bumper spring grain harvest and quantity of pork consumption has increased. Marketing plans should be actively fulfilled, and in places where live hog purchases overfulfill plan, more pork should be made available in an effort to avoid occurence of a situation of "difficulty in selling pork." Purchasing units should also fully tap storage potential, borrowing some old storage lockers and erecting some simple storage sheds to do the utmost in keeping more pork in order to improve pork supplies in villages during the summer harvest and summer planting.

2. Reliance on Close Coordination With Units Concerned. Large and small freezer plants that are "focal points" should seize this "golden season" to tap potential, accept more hogs, slaughter more hogs, and store more hogs. Other light industrial units that use hogs as raw materials should alsl proceed from the overall situation in receiving hogs according to plan. Transportation units should give careful attention to safe hauling to avoid deaths of live hogs so as not to create unnecessary economic losses.

3. Reliance on the Support of the Broad Masses of Commune and Brigade Cadres and on Households Selling Hogs. As peasant living standards have improved and rural systems of responsibility have been implemented, peasant pork consumption has spurted during the time of summer harvest and summer planting; consequently, a staggering of the time of sales of live pork to

the peasants is required, with some pork being kept until ate July and August so that it can be slaughtered on the spot and supplied at the appointed time. This way also helps accumulate hog dung to meet the needs of the late rice crop for organic fertilizer. Commercial units have already made a great amount of preparation to purchase live hogs, and the "main door for the purchase of hogs is wide open." The broad masses of peasants need not believe rumors, but should sell their hogs in batches in accordance with the feeding practices in each jurisdiction, and should coordinate with and support units dealing in foodstuffs to do a good job in purchasing hogs.

Solution to "difficulty in selling hogs" bears on stabilizing and promoting live hog production, and on preserving peasant enthusiasm for hog-raising. That it is the concern of all quarters and of the peasants is only as it should be. If reliance is placed on all levels of party and government leaders, with the broad masses of staff and workers in commercial units actively making efforts, and both units concerned and rural communes and brigades giving vigorous support, the situation of "difficulty in selling hogs" during the small peak season in hog procurement can be avoided.

RENEWED EMPHASIS ON ORGANIC FERTILIZER NOTED

Official's Statement

Hangzhou ZHEJIANG RIBAO in Chinese 6 Jun 82 p 1

[Text] "A large volume of investigation materials attest that increased collection and increased use of organic fertilizer are measures of strategic significance for assuring sustained increases in agricultural production, and all levels of leaders should be certain not to treat this as unimportant." This was an observation that Provincial CCP Committee Secretary and Deputy Provincial Governor Chen Zuolin [7115 0155 7207] repeatedly emphasized in a statement he made yesterday to the newspaper's correspondent. He has required rural leaders at all levels throughout the province in the course of organizing forces to diligently grow and care for the early rice crop, use June's advantageous conditions of numerous sources of fertilizer to go all out in stirring the masses to the widespread launching of a summer fertilizer collection campaign to create fine conditions for increased yields from this year's late rice harvest and for a bumper harvest for the year as a whole.

Comrade Chen Zuolin pointed out that basic soil fertility had an extremely great deal to do with how well farm crops grow and, in this sense, to give attention to the soil's basic fertility is the same thing as giving attention to the capital construction of farmlands. Increased collection of fertilizer is no expedient measure, but is rather a basic issue of strategic importance; it is not a trivial matter but an important one. During the 1960's no phosphate fertilizer was applied even to green manure plants in the Hangzhou and Jiaxing lake area, but by the mid-1970's the paddy rice also lacked phosphate. Today some places have also discovered a lack of potash. A small number of places in the area around Ningbo and Shaoxing have recently discovered a lack of zinc. The basic reason for the occurence of such situations is the serious proportional imbalance in fertilization with organic and inorganic fertilizer. The former traditional pattern of using mostly organic fertilizer has undergone great changes. If this continues, there will be no end of trouble in the future. This is the situation in high yield areas, and in low yeild areas the situation is more serious. Today Zhejiang Province has more than 3 million mu of "low yield fields" with normal annual yield as low as 800 jin per mu. The yields from these low yield fields are low because the soil itself is farily seriously abnormal; its structure is very poor, and it is seriously lacking in elements. Unless these fields are improved and their basic fertility increased, they will never get rid of their stigma as low yield fields. Recently I learned at the Jiaxing Prefecture Institute of Agriculture that from 1973 up until last year, in years of fairly severe natural disasters and in years of fine weather alike, their several mu of three crop experimental grainfields produced yields of more than 2,000 jin per mu for 9 consecutive years. Aside from some scientific farming methods used, the main reason for this was the serious importance they attached to equitable fertilization with both organic and inorganic fertilizer, and the serious importance they attached to improving the soil's basic fertility. Were everyone to understand this rationale, they would not regard the collection of fertilizer as "a platitude," but rather would give it attention as a major link in increasing present scientific levels of farming. Happily, today there are some counties that have done just this. We will introduce and promote their experiences in a future issue of the ZHEJIANG RIBAO. The Provincial CCP Committee wishes that all counties would do this.

Comrade Chen Zhling continued by pointing out that it is in the late fall crop that the lack of organic fertilizer shows up particularly seriously, and particularly in the late rice crop. The late rice crop has no green manure as a base fertilizer, and the area on which river mud is used as a base fertilizer has contracted greatly. Units concerned have found that unless decisive measures are taken, possibly 5 to 6 million mu of late ricefields will remain unplowed and unplanted this year. This is one of the major reasons why the output of late rice does not rise or is inconsistent in some counties. In analysing this fall's production situation, simultaneous with full consideration of all advantageous conditions, all levels of party and government leaders must note this point clearly and handle it conscientiously.

Finally Comrade Chen Zuolin placed a specific requirement on all jurisdictions. He said that June is the time for field care of summer crops, and leaders at all levels should take firmly in hand this favorable opportunity to go all out in stirring the masses to enlarge sources of fertilizer, to do mass gathering of mud fertilizer, and to start an upsurge in the increased gathering of mud fertilizer. He required that effective action be taken to increase the planting of sesbania and such summer green manure, and of fine duckweed, to dedicate an area to this, and to encourage the return of rice straw to the fields. In short, cities, towns, and villages should link up in a summer patriotic sanitation movement to run a mass campaign lasting a few score days to gather fertilizer. This would not only solve difficulties with insufficient base fertilizer for the late rice crop, but would make a good beginning in improving the soil's basic fertility. Comrade Chen Zuolin said that in order to make sure that these actions will be rapidly carried out everywhere, we will intensify inspections supervision, and goading, commend the advanced, spur the laggards, and strive for balanced development.

Two Experts' Views

Hangzhou ZHEJIANG RIBAO in Chinese 8 Jun 82 p 1

[Text] Zhejiang Province's noted soil fertility experts and professors at Zhejiang Agricultural University, Sun Xi [1327 5032], and Yu Zhenyu

[0205 7201 6276] expressed their separate views to the correspondent on the issue of rational fertilization.

The two experts believe that one of the problems existing today in the use of fertilizer is the great importance accorded chemical fertilizers and the slight importance accorded organic fertilizer, which has brought about a situation of proportional imbalance between the two kinds of fertilizer. They said that we should have two goals in fertilizing. One is to provide nutrients to the crops to increase yields; the other is to increase the soil's organic content and to nurture its fertility. Though fertilization with large amounts of chemical fertilizers can win high yields for a time; it does nothing for nurturing soil fertility and may even not be good for the nurturing of soil fertility. Calculations based on isotope tracing shows the utilization rate of chemical nitrogenous fertilizer to be a general 50 percent, and less in the case of phosphate. This shows that most of the nutrients that plants absorb are those that existed in the soil originally, and which are supplied by the soil. Therefore, nurture of soil fertility is a major basic matter, and in nurturing soil fertility, only organic fertilizer can do the job.

The two experts explained that the water, fertilizer, air, and heat in the soil all have to be coordinated if it is to be like a man in the prime of life, alive and strong. Coordination of water, fertilizer, air and heat is done by their conversion by organic fertilizer into humus. Organic fertilizer is like glue that binds soil granules together into "masses" of different sizes to borm a "granular structure." Such a structure resolves the contradiction of mutual jostling of water and air, making the soil friable and increasing its capabilities to conserve fertility and provide fertility. Thus, a good structure is the basis for soil fertility, and organic material is the material foundation for this kinds of structure. Organic material is also an "energy material;" it is food for micro-organisms, and micro-organisms play the "leading role" in promoting a series of soil fertility development processes. For example, soils contain numerous nutrients that plants are unable to absorb directly. For example, the soil content of potash may run from 2.1 to 2.3 percent, which is to say that there will be between 600 to 700 jin per mu. But it is a "mineral," requiring weathering and "extraction" by micro-organisms before it can become a soluble nutrient and be absorbed by crops.

Therefore, in order to make the soil fertile, it is necessary that micro-organism families proliferate, and this requires use of organic fertilizer.

Buy why is it that organic fertilizer cannot nurture soil fertility? The two professors answered by saying that fertilization solely with chemical fertilizer provide micro-organisms with a source of nitrogen enabling them to proliferate greatly. However, for each part of nitrogen micro-organisms use to build their body cells an expenditure of 25 parts of organic carbon is required. If there is insufficient organic fertilizer, they can only break down the organic material in the soil to obtain energy. Consequently, longterm fertilization with chemical fertilizer with no increase in organic fertilizer must inevitably create a decline in the soil's organic matter and impair soil fertility. The rate of yield increase per jin of nitrogenous fertilizer also drops. Experiments have shown that for every 37 jin of ammonium sulfate used, between 2,000 and 2,500 jin of farmyard manure should be added in order to check depletion of the soil's organic materials and humus. Therefore, chemical fertilizer has to be used in combination with organic fertilizer if the soil is to maintain its fertility and the benefits of increased yields from chemical fertilizer increased.

Tow two professors pointed out that to get high yields from low yield areas, organic fertilizer to nurture soil fertility would have to be relied upon; to get consistent yields from high yield areas and to get continued increases in yields, it is even more necessary not to neglect organic fertilization. When yields are high, that shows that the crops have taken many nutrients from the soil, and unless they are promptly replaced, and the organic content of the soil falls, it will not be easily revived. In Zhenjiang where rainfall is great and temperatures high, organic fertilizer decomposes rapidly. In addition, the multiple cropping index is high, so the amount of organic fertilizer applied to the soil has to be somewhat greater.

The two experts also noted that Zhejiang Province enjoys advantages in its workforce and in its farming techniques for large scale use of organic fertilizer. By making use of these advantages to invest in the soil very great benefits can be realized. They suggest that in order to encourage the peasants to use more organic fertilizer, specific policies should be formulated, and that promotion of the use of organic fertilizer should be made a part of the technical responsibility system for farm technicians.

SOURCE: Tianjin ZHONGGUO XUMU ZAZHI [CHINESE JOURNAL OF ANIMAL SCIENCE] in Chinese No 1, 5 Feb 82 pp 9-12

ABSTRACT: The distribution of goats is extensive in China. In more than half of the provinces, the number of goats exceeds that of sheep and in some southern provinces, where raising sheep is not feasible but raising goats is possible. There are only about 8 billion goats in China, however, 61.3 percent in farming areas and 23.5 percent in pastoral areas, with the remaining in mixed areas. With sheep, 60.2 percent are in pastoral areas to prove that goats are distributed mainly in farming areas. Geographically speaking, 41.8 percent of the goats are in the south, 58.2 percent the north; and 28 percent in the coastal areas and 72 percent the inland areas. The major breeds of goats in China, the natural conditions of their areas of distribution, their morphology, size, and weight, their fur, wool, meat, and/or milk producing properties, their reproductive capacities, and the effects of ecological condition on the various goat breeds are summarized.

TITLE: "Effects of Feeding Porkers With Mixed Feeding Containing Primarily Agricultural By-products"

SOURCE: Tianjin ZHONGGUO XUMU ZAZHI [CHINESE JOURNAL OF ANIMAL SCIENCE] in Chinese No 1, 5 Feb 82 pp 21-22

ABSTRACT: Based upon the feed resources of Zhenhai County, 3 mixed feeds are prepared containing mainly agricultural by-products to study feeding results. From Apr to Sep, 2 of the mixed feeds were compared at the pig farm of Yapu Commune, aside from the experiment carried out in the bureau. The 3 type of mixes contain barley, raw bran, rapeseed residue cake, fish powder, corn, cottonseed residue cake, dry sweet potato, sea shell powder, edible acid, in varied ratios. For comparison, 2 porkers were used for each group. Results indicate that the daily weight gains vary from 461 g to 537.3 g/pig, and an increase of the protein content with a reduction of the fiber content can reduce the feed consumption to raise the rate of utilization of the feed material.

TITLE: "Structural Model of Oasis Agricultural System in a Desert Region: The Linear Formula of the Structure of Agriculture, Forestry, and Animal Husbandry of Shihezi Reclamation Region, Xinjiang"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 6, 24 Jun 82 pp 15-17

ABSTRACT: Based upon the process of developing the Shihezi Reclamation Region, the authors propose in the paper a concept of oasis agricultural system in a desert region to acknowledge the place and function of forestry and animal husbandry in the special environment from the viewpoint of ecology. On the basis of the historical lessons learned from developing that region and the survey data accumulated there, a model is also established with respect to the linear proportion of agriculture, forestry, and animal husbandry. Several development formulas are analyzed on the computer, using the practice of developing that region as the criterion to evaluate and examine the reasonableness of each formula for determining the final selection of the model system. The objective is to obtain the optimal economic benefit under the premises of maintaining the ecological stability and equilibrium. The Shihezi

[continuation of ZHONGGUO NONGKEN No 6, 1982 pp 15-17]

Reclamation Region was surveyed, designed, and constructed in the 50's, to compose 19 farms (communes) of 5 irrigation districts. The agricultural oasis had a total of 5 million mu of land and 2.95 million of which were cultinated. At present, there are 550 thousand inhabitants and 210 thousand of them work for the State farms. After the system was created from the desert, an oasis was established throughout the 60's to become a reasonable structure and the economic gains were very high. In the 8 years of 1958-1966, 26.7 hundred million jin of grains, 1.76 million jin of cotton were accumulated for the State, amounting to a profit of 1.492 billion yuan. Then, came such unfortunate slogans, during the cultural revolution, as "Good land is not to be used to plant trees." and "Rotating grass with crops is a foreign dogma." etc. and the forest zones and alfalfa meadows of the reclamation region were destroyed. The production dropped severely and quickly. The yield was reduced from 400 jin/mu of the early 60's to about 200 jin/mu in the 70's. In the 60's 4,500-5,000 animals were sustained by each 10 thousand mu of grassland, by the 70's the number of animals was reduced down to 1,500-2,000 heads of sheep per 10 thousand mu. In order to produce more grain to eat, alfalfa meadows were turned over for cultivation. These measures caused the profit situation to change to continuous losses. In the 11 years, the total loss of the State farms amounted to 3.84 hundred million yuan. In 1977, a new formula was adopted to restore the ecological balance of the region. It is estimated that when the optimal formula is completely realized, the current profit of 20 yuan/mu will be raised to 50 yuan/mu. The model formula is discussed.

TITLE: "Current Mission of China's Agricultural Engineering"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 2-4

ABSTRACT: With the approval of the State Council, the Ministry of Agriculture has established the Bureau of Agricultural Engineering and the China Research and Design Academy of Agricultural Engineering, as well as encouraged the establishment of the Agricultural Engineering Society since 1979, to promote the application of modern engineering technology in agriculture. Aside from the principle of achieving economic benefits and developing the field to suit China's own special conditions, the author provides an outline of the following tasks: (1) Breed superior crop varieties; (2) Carry out research on highly effective insecticides and herbicides of low toxicity to protect plants; (3) Change the structure of chemical fertilizer application and practice reasonable application of fertilizer; (4) Provide rural villages with needed fuels and resolve the contradiction between fuel, feed, and fertilizer by comprehensive utilization; (5) Design for the needs of househood auxiliary industries; (6) Work for the engineering of farm by-products processing; (7) Develop natural resources survey of rural villages. This paper is written on the basis of a speech delivered by the author at the Expanded Conference of Board of Directors of the Chinese Agricultural Engineering Society.

TITLE: "Experts on China's Future Agricultural Construction Work: Unlimited Promise of Agricultural Engineering"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 5-6

ABSTRACT: The author defines agricultural engineering as a polytechnical and comprehensive engineering, spanning across many specialties to utilize newly emerged techniques of various types of engineering to develop, utilize, and protect natural resources so as to raise agricultural productivity, improve the rural environment, and shorten the distance between the workers and the farmers and between the cities and the countryside. The paper explains in some detail the above definition of the field. A limitless and bright future is predicted for this new field.

TITLE: "Experts on China's Future Agricultural Construction Work: Make Many Contributions To Develop Agricultural Engineering"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 6-7

ABSTRACT: Centering upon the government's report delivered by Premier ZHAO Ziyang at the Fifth Plenum of the Fourth People's Congress, the author sets forth in the paper the tasks of agricultural engineering for the purpose of freeing China gradually from the self-supplying and self-sufficient type of agricultural production of the past to develop gradually toward a future merchandise-producing agriculture. The existing cultivated land, and the vast mountains, hills, grassland, lakes and coastal seas must all be reasonably and fully utilized. Just as Premier ZHAO said, land utilization engineering, agricultural energy source engineering, agricultural environment engineering, agricultural construction engineering, food and food processing engineering, etc. are all parts of agricultural engineering. Efforts must, therefore, be exerted to contribute to its development and it must not be allowed to fail our expectations.

TITLE: "Experts on China's Future Agricultural Construction Work: Extend Agricultural Engineering Technology to Accelerate the Development of Agriculture"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 7-8

ABSTRACT: Since the 11th Plenum of the Third Congress of the party, agriculture in China has gradually and steadily been developed into a new era, but in order to develop agricultural production still further to bring about a prosperous rural economy, it is necessary to apply extensively scientific technologies to the following 3 aspects: (1) Developing the potential productivity of plants and animals with technologies of bio-sciences; (2) Improving and creating environmental conditions favorable for the growth and development of animals and plants and techniques of processing and storing agricultural by-products; (3) Business management of agricultural production to raise the economic benefits. Ways with which efforts are to be made at present toward the above goals are discussed in some detail.

TITLE: "Experts on China's Future Agricultural Construction Work: Welcome the Coming of a New Year and March Forward in a Firm Stride"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 8-9

ABSTRACT: The work of the Agricultural Engineering Society in the past year is generally summarized to be organizing some scientific discussion meetings, starting some courses of study and some training classes, launching projects of popularizing sciences and technologies, publishing some journals, and compiled some books. In the new year, the Expanded Conference of Board of Directors has suggested the development of a program of answering technical inquiries, introducing techniques of processing, transporting, and maintaining the freshness of farm products, gradual standardization of the terminology and work procedures of agricultural engineering, and establishing some specialty committees and strengthening international scientific exchanges, etc. Finally, due to the traditional separation of departments and professions, some weak links and blanks still exist in the field and this shortcoming is especially reflected in the arrangement of specialties in schools of higher and intermediate education. This is a problem requiring an urgent resolution.

TITLE: "Experts on China's Future Agricultural Construction Work: Make It a Good Society [Scientific Association] to Develop The Field"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 9-10

ABSTRACT: The field of agricultural engineering being developed in China is not yet a familiar subject to all. It still sounds like a newfangled thing. In reality, it has contributed to agricultural production for a long time and has a long and honorable history. It may be said that agriculture and agricultural engineering are inseparable friends. For example, the irrigation structure in Dujiang of Sichuan was built 2500 years ago and remains a world famous large scale agricultural engineering. The author goes on to say that as a new scientific field, agricultural engineering had its start in 1907 when the society was established in the USA and a department was established in the University of Iowa as well as the University of Nebraska. Although the Chinese Agricultural Engineering Society was established as late as 1979, it now has more than 500 members and branch societies have sprung up in 29 provinces, cities, and autonomous regions. The author urges all members to unite to develop and promote the field.

AUTHOR: HU Qinling [5170 2953 1545]

ORG: Deputy Director, Bureau of Seeds, Ministry of Agriculture

TITLE: "Current Condition and Future Development of Seed Processing Engineering in China"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 11-13

ABSTRACT: Machine processing and sorting of seeds, including threshing, drying, and cleaning, is a new task. After the goal of seed processing mechanization was brought up at the National Seed Work Conference in 1975, obvious accomplishments have been obtained in these short years, considering the fact that it started out from nothing. In 1976-77, some sample machines were introduced from E.Germany and Switzerland and manpower was organized to draw, imitate, and manufacture. In 1978, the machines began to be extended. Today, the country has more than 5000 seed sorting machines of all types, 770 high freqency seed treatment machines, 850 low frequency current treatment instruments, 260 seed drying machines, and more than 1400 drying rooms, drying chambers, and drying pits. At present, all counties of 29 provinces, cities, and autonomous regions have machine seed sorting capability. The quantity of seeds that are machine processed has increased from the 2 hundred million jin of 1978 to 12 hundred million jin in 1980, to exclude from just wheat, rice, and corn to include Gaoliang, millet, beans, flax, and green manure. Obvious economic benefits have also been obtained; due to the improved quality of seeds, less seeds are used for planting. The 10-15 percent broken seeds after sorting are used mostly as food with some as feed. These seeds would not germinate and would have been wasted if they are used for planting. The yield increase is estimated at 5-10 percent. Of course, the seed selecting labor is also considerably lessened.

TITLE: "Investigation of Several Problems in Rural Energy Source Research"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 18-20

ABSTRACT: Most recently, the author participated in the work of compiling and writing the book, RURAL USES OF ENERGY and the work of rural energy survey and encountered several real problems as follows: (1) The number of firewood-deficient households commonly figured to be 8 billion, amounting to 47.7 percent of farming households. This is not in fact a realistic figure because many of these households may be short of firewood a few months in a year only, as the concept of firewood includes dry stubble, wood shaving, husk, etc. Certain indices are proposed to arrive at a realistic figure of shortage for every prefecture, county, commune, or brigade. (2) The effective heat value needed for daily living of a farm househood varies from place to place. It is suggested by ZHANG Zhengmin [1728 2973 2404] of Research Institute of Energy Sources Chinese Academy of Sciences that to maintain a minimum standard of

[continuation of NONGYE GONGCHENG No 1, 1982 pp 18-20]

living, 424 kg of coal is needed per farmer per year. This figure may be converted into an effective heat energy of 5000 kcal. The author's survey indicates that in Rugao County of Jiangsu Province, for example, the actual needs are estimated at 3500-3800 kcal. (3) Standard heat value of farm "firewood" also varies a great deal. For example, the heat value of stubble is thought to be 3400 kcal but related department in Zhejiang Province claims that the local stubble is valued at 2000 kcal, while the average heat value of coal in Jiangxi Province is valued only at 3700. It is important to set realistic equivalent values for all different types of fuels and "firewood" so that in the North and the South everyone can speak the same language. Finally, the paper also deals briefly with problems of estimated production of firewood-producing forests, small hydroelectric power stations, small coal mines, and other related problems of operation, management, ownership, etc.

TITLE: "On the Effects of Energy Utilization For Agricultural Production in Xinjiang"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 20-23, 10

ABSTRACT: The sources of energy for agricultural production in Xinjiang is currently composed of chemical fertilizer, oils, electric power, agricultural machines, seeds, manpower, and animal power. In 1979, 546.698 thousand tons of chemical fertilizer were applied, the production of which consumed 381.916 thousand tons of standard coal. The total oil materials used at the farms was 274 thousand tons, about 70 percent of which was for agricultural production, the equivalent of 261.8 thousand tons of standard coal. For farming machinery, including tractors, implements, trucks, irrigation and drainage equipment, etc. about 198.8 tons were used. Estimated at an energy consumption of 7 tons of standard coal to manufacture 1 ton of farm machinery, the consumption may be converted into 139.1 thousand tons of standard coal, assuming the useful life of the machinery being 10 years. The electrical power used was 37.569 billion kwh which may be converted to 95.623 thousand tons of standard coal. The manpower used for agricultural production is 2.95 million man-days. The energy contributed by these workers may be converted to 63.72 thousand tons of standard coal. There were 972,490 draft animals working for agricultural production and the estimated

[continuation of NONGYE GONGCHENG No 1, 1982 pp 20-23, 10]

total energy contribution may be converted to 60.796 thousand tons of standard coal. For agricultural production, 35.086 billion kg of seeds were used. Considering the energy needed to produce 1 kg of seeds to be 0.2 kg of standard coal, the energy consumed for the seeds is the equivalent of 70.17 thousand tons of coal. The author concludes, based upon the data thus furnished, the major problems may be said to be low utilization rate, improper application, and a disproportionate ratio, as far as the energy consumption for agricultural production in Xinjiang is concerned. First, too much energy is consumed through chemical fertilizer application, amounting to 36 percent of total. Soils of Xinjiang have a low active phosphorus content; therefore, the ratio of nitrogen and phosphorus should be 2 : 1, instead of the present 4 : 1. In terms of ecology and environmental and soil protection, the long term goal should be organic farming. There is a very great potential in the possibility of reducing the consumption of petroleum fuels in Xinjiang. The paper also offers varieties of ways to reduce the quantity of seeds used for planting and to increase labor productivity. In terms of productivity, the energy consumption of draft animals through the consumption of feed is 4 times higher than a farm machine. The author is in favor of using the feed to raise animals as meat and developing machines to take the place of draft animals.

TITLE: "Lectures on System Engineering in Agriculture: I. General Discussion of System Engineering in Agriculture"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 1, 25 Feb 82 pp 32-37

ABSTRACT: In the early 19th century, with the discoveries of energy conversion, cells, and the theory of evolution, mankind began to notice that nature is a unified entity of events and processes that are interrelated, interdependent, interacting, and mutually limiting. This idea of unified entity is an idea of "system." System engineering is different from mechanical engineering in so far as it also involves completion, organization, planning, arrangement, etc. to provide decisions, formulas, and procedures for the purpose of realizing the optimal design, the optimal control, and the optimal management. System engineering of agricultural production; therefore, does not limit to breeding a given superior crop, producing a certain insecticide, a machine, or chemical fertilizer. It concerns the research, orgnization, and arrangement of planting, manpower, animal power, implements, fertilizer, capital, etc. for the purpose of obtaining the highest total yield and the optimal economic benefit most reasonably and effectively. This definition of system engineering in agriculture is detailed.

TITLE: "Discussions Concerning the Prospect of Agricultural Development in China"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2, 25 Apr 82 pp 2-5

ABSTRACT: Before discussing the prospect of agricultural development in China, it is necessary to assess correctly the natural conditions of China and the current conditions of agriculture. The size of land and surface water, the number of species of seed plants, the number of species of land vertebrates, the number of species of marine and freshwater fish, the total yield of major agricultural crops, and the cultivated field, forest land, and grassland per capita are reviewed as well as China's geographic location, climate, uneven distribution of basic resources, acreage subject to frequent flood and drought damages, and the size of land occupied by cities, transportation, and industry and wasteland yet to be reclaimed. The paper concludes that the natural conditions of China dictate that the direction of future development should be multiple and comprehensive operation of farming, forestry, animal husbandry, auxiliary industry, and fishery and China's agriculture must not be limited to cropping. On the basis of the experience of the past 3 decades, the paper discusses, in general terms, the relationship between industrialization and agricultural development, difficulties and strategies of agricultural development, and the key motive power, i.e. the economic benefit for the farmers, necessary for agricultural development.

TITLE: "On the Important Function of Construction Engineering in Agricultural Production"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2, 25 Apr 82 pp 6-7, 26

ABSTRACT: Agricultural modernization means instead of depending entirely upon nature, exerting efforts to create an environment, i.e. to change the natural condition to being favorable for fast and satisfactory growth of animals and plants on the limited land and other resources. It is, therefore, necessary, to emphasize constructive engineering to raise the agricultural productivity to include the development of greenhouse culture, industrialized poultry and animal hunsbandry, feed processing, seed processing, and food processing, to build various warehouses to store and keep fresh various agricultural products, and to design and construct comprehensive engineering structures for the regeneration of energy sources. If these items of construction engineering are not included in today's development agenda, the future of agriculture will be greatly affected. The paper proceeds to detail the items of construction for agricultural development.

TITLE: "Introduction and Development Condition of Plastic Film Ground Cover Cultivation Technique in China"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2, 25 Apr 82 pp 8-9

ABSTRACT: Traditionally, straw, horse manure, weed stubble, sand, and stone were used in China as a ground cover to protect moisture, fertility, and temperature. In the middle of the 20th century, with the development of high molecular compounds, the technique of using polyvinyl film was created. Japan was the first to carry out research on the subject, followed by many other countries to reap various degrees of benefits. In the winter of 1978, the technique was introduced to China from Japan. The Bureau of Science and Technology of the Ministry of Agriculture organized some units in various provinces, cities, and autonomous regions of the country in 1979 to experiment with the technique in 660 vegetable fields and obvious benefits of yield increase and early ripening were obtained. In 1980, the experimental acreage was quickly expanded to 25,000 mu of vegetables, peanuts, cotton, rice, melons, and fruits. In 1981, the acreage was developed to 220,000 mu and the technique was experimented with more than 70 crops. At present, the value of the technique has been affirmed for more than 30 types of crops. The application of the thin plastic film ground cover technique in various parts of China is briefly discussed.

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2,25 Apr 82 pp 24-25

ABSTRACT: On the basis of some tube-supported plastic tents introduced from Japan in 1979-80, the Shijiazhuang Institute of Agricultural Modernization Chinese Academy of Sciences proceeded to carry out comprehensive research on their structure, properties, and experiments of their use in crop culture. In 1981, the PGP5-1 was designed and the single beam prototype plastic tent suitable for the conditions of China was manufactured by Shijiazhuang Construction Machinery Plant. At present, it is being produced in small batches for the use of various regions of the country. The structure, properties, and characteristics of the plastic tent, its range of application,and beneficial effects are briefly reported.

AUTHOR: WU Chengzhong [0702 6134 1813]

ORG: Jiangsu Provincial Science Committee

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2,25 Apr 82 pp 27-30

ABSTRACT: On the one hand there is a serious energy shortage problem in Jiangsu and on the other hand there is still a great deal of waste of energy. A survey, reported in the paper, reveals the number of households of a typical commune to be 999 in 1965 and 985 in 1980, the income to be 129.01 per capita in 1965 and 228.65 in 1980.The energy consumption in 1980 is calculated to be the equivalent of 855.4 kg of standard coal per year per household of 5 persons on the average for daily living. Due to the inefficient old fashioned stoves, the waste is about 10-15 percent. Energy consumption directly and indirectly for agricultural production is the equivalent of 3.98 million tons of standard coal, with an average increase of 16.11 percent while the increase of the value of agricultural products has only been 8.69 percent per year. The energy resources are calculated at the equivalent of 18 million tons of standard coal per year, of which bio-material energy amounts to 98 percent. Due to the high population density of the province, compared with other provinces of the country, the energy resource is only the equivalent of 360 kg of standard coal, much lower than the 600 kg per capita nationwide. The rural villagesof the province still have resources of solar, wind, and peat energy awaiting reasonable development, however. In that sense, energy self-sufficiency remains a possibility in the province. Ways of resolving the energy shortage problem are suggested.

TITLE: "Lectures on System Engineering in Agriculture: II. System Analysis and System Models in Agriculture"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 2,25 Apr 82 pp 40-44, 39

ABSTRACT: Analysis of an agricultural system may provide the scientific basis for establishing a new system more suitable for the agricultural ecology and economic needs. Two examples are given: (1) The Lianyuan Prefecture Institute of Agricultural Sciences analyzed the yield, ecological property, transplanting density, fertilizer application level, etc. of hybrid early rice in 36 farming areas to produce polynominal regression equations (a mathematical model) to compute the target function of the various desirable properties. Using a computer, 86 formulas were chosen from 1028 suggested formulas before analyzing other experimental data to produce, finally, 2 high yield formulas, which have now been applied successfully in production. (2) A mountain production team of Beijing was used as the target to analyze types of energy resources and conditions of conversion utilization. The

[continuation of NONGYE GONGCHENG No 2, 1982 pp 40-44, 39]

energy needs were duly surveyed and analyzed to produce an energy flow chart and a linear planning model. With the highest net gain as the target of the system, an optimal formula of solar energy comprehensive utilization plan was designed to make it possible for the capital investment to be recovered in 4 years. Applications of system analysis and mathematical models in the decision-making process of agricultural production are briefly introduced.

TITLE: "Investigation of the Oversummer Principle of Wheat Stripe Rust Pathogen in Yunnan Province"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 1-7, 22

ABSTRACT: Wheat stripe rust is a major disease in central, western, and northwestern parts of Yunnan. In a mild year, about 1 million mu are involved, amounting to 13 percent of the wheat acreage. In a severe year, such as 1981, 40 percent of the acreage, i.e. 2.7 million mu of wheat were affected to result in a yield reduction of 150 million jin. In the summer of 1979, the Plant Protection Institute of the academy carried out an investigation of the oversummer condition of the stripe rust pathogen in such severely affected areas as Anning, Lijiang, etc, and stripe rust disease was discovered on self-sown wheat and summer wheat and the same was observed during a follow-up investigation in 1980 to prove that wheat stripe rust pathogen can oversummer in Yunnan in such cool areas as Zhongshan, Gaoba, etc. In 1981, a team was organized by the institute and the Yunnan University of Agriculture to carry out an extensive survey through Kunming, Yuqi, Dali, Lijiang, Baoshan, Chuxiong, Qunjing, etc. totaling 18 communes in 7 counties to determine the areas of oversummering pathogens. Results of the 3 year study, 1979-81, are reported.

TITLE: "Epidemiological Reasons of Wheat Stripe Rust in Dali Prefecture and Ways of Its Prevention and Control"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 8-15

ABSTRACT: Dali Prefecture is located between 24°40' and 26°47' N. Lat. and is warm in the winter and cool in the summer, with plentiful rainfall. It is a wheat high yield region as well as a region of frequent summer wheat stripe rust incidences. Since the 60's, there have been 5 severe epidemics in 1963, 73, 79, 80, and 81 with ever enlarging areas of involvement, from 233.3 thousand mu in 1979 to more than 800 thousand mu in 1981. Analyses reveal that the 3 factors of wheat breed, pathogen, and environmental condition contrubute to the severe epidemics. Since 1979, the species composition of the pathogens have changed and highly toxic species have become dominant. The mountainous and semi-mountainous aroas of 2000-23000 m.in elevation are favorable for large quantities of oversummering pathogens, taking the form of summer spores to reproduce and infect continuously. Preventive measures of reasonable arrangement of breeds and cultivation techniques are extensively discussed.

TITLE: "Experimental Use of Perforated Plastic Film to Cultivate Rice Seedlings"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 19-22

ABSTRACT: Although using plastic film to cultivate rice seedlings has the advantages of producing stronger seedlings and reducing the number of rotton seedlings there are also shortcomings of having too high a temperature on clear days, and tender seedlings of weak resistance due to moisture saturation under the plastic cover. In May 81, the author and colleagues experimented with growing rice seedlings in a tent made of plastic film with prepunched holes. Plastic films in dark blue, light blue, and white were used with an open-air seedbed as the first control and dark blue plastic film without holes as the second control. The holes are punched in size of about 1 cun in diameter and 1 x 1 chi in distance. After seeding on 26 May, the films are used to make tent covers immediately. Results indicate that seedlings grow best under the dark blue perforated plastic film cover. The quality of the seedlings, the growth and development period of the seedlings, the different temperature conditions under the different covers, the yield structure factors of the seedlings, etc. are among the observed data reported in the paper.

TITLE: "Brief Introduction of a High Yield Breed of Rice, Dianyu No 1"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 23-25

ABSTRACT: Dianyu No 1 is a hybrid rice introduced from the Yunnan Provincial Rice Cooperative Group in 1974 by LI Weicai [2621 3634 2088] a technician of the Dali County Agricultural Technology Station. The hybrid material was propagated in Zhoucheng for selective breeding to become the high yield,medium maturing, short stalk, numerous spike type intermediate Keng variety. Since 1977, it has been tested, demonstrated, and extended for 6 years. Its yield has been high and stable in warm or cold years, in sandy or clay soils, and in all areas of 1970 to 2080 m in elevation. In 1979, 500 mu were extended in the county and the yield was 1,368 jin/mu. In 1980, 2160 mu were cultivated and the yield was 1429.466 jin/mu. In 1981, 5261 mu were planted and the yield was 1457.4 jin/mu. Dianyu No 1 is beardless. The stalk is 80-90 cm in height. The spike is 15-16 cm in length, with 90-100 grains per spike. The fruiting rate is about 90 percent. The grain is short and round, weighing 23-24 g/1000 grains. The husking rate is 78 percent. The rice is white and slightly transparent, and very tasty. The key cultivation techniques are described.

ORG: Quqing Prefecture Bureau of Agriculture

TITLE: "Varied Techniques to Take Advantage of Superior Conditions for the Yield Increase of Maize"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 33-35, 41

ABSTRACT: From the late 50's to the early 60's (1957-64) due to the influence of leftist ideas, practice became separated from reality and there was the mistaken attempt of changing coarse grain to fine grain, i.e. converting uplan fields to paddies. The maize acreage was continuously constricted and the unit yield stayed the same. The natural conditions of Quqing, i.e. the elevation, the weather, and the soil fertility, are suitable for the growth of corn and the condition of water is less than favorable for paddy rice, however. Since then, the maize acreage has been increased yearly. In 1980, it was 2.394+ million mu to produce a total yield of 126 hundred million jin. In 1981, the months of Jun and Jul were cool and rainy and the Sep was dry but the total corn yield was still 102 hundred million jin. For the production of corn, the prefecture is divided into 3 regions: the high yield region of a unit yield of above 800 jin/mu, the medium yield region of a unit yield of 500-800 jin/mu, and the low yield region of a unit yield of less than 500 jin. The breeds, the cultivation technique, the fertilizer application, etc. are all designed differently to meet the requirements of the 3 different regions. Furthermore, green manure is regularly cultivated and the accumulation of farm manure encouraged. Chemical fertilizer is applied reasonably, with emphasis on phosphate fertilizer. These and other measures adopted in the prefecture to bring about successful yield increase of corn in recent years are introduced.

TITLE: "Important Measures to Increase the Unit Yield of Sugar Cane in Yunnan"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 25 Mar 82 pp 36-41

ABSTRACT: Since the liberation, the sugar cane acreage has been expanded from 107 thousand mu to 633 thousand mu in the province and the total cane production from 275 thousand tons to 1,844 thousand tons. The increase in the unit yield is very negligible, however. It is only from 2.52 tons to 2.70 tons/mu, while the average for the world is 3.58 ton/mu with the highest at 11.25 tons/mu. Following an analysis of the 4 factors of the yield structure: the number of effective stems, the height of the stalk, the diameter of the stem, and the weight of the stem, the paper concludes that the chief reason for the low yield condition in Yunnan is the fact that the stalk is not sufficiently high. The following mesures are suggested to overcome the problem: (1) Cultivate some autumn sugar cane in suitable areas; (2) Extend the technique of cultivating seedlings for transplanting; (3) Manage perennial roots well; (4) Carry out an 8-item regimen of cultivation technique faithfully.

TITLE: "Water Conservancy Engineering Must be Combined With Afforestation of the Source of Water"

SOURCE: Beijing ZHONGGUO LINYE [FORESTRY IN CHINA] in Chinese No 6, 5 Jun 82 pp 4-5

ABSTRACT: Although the rainfall of Hainan Island is very rich its distribution is not even, with 80-90 percent of it concentrating in the period from May to Oct. From Nov to Apr, the dry season lasts 4 to 6 months, with only about 10-20 percent of the precipitation of the year. During the dry season, the high temperature and intense sunlight cannot be used to serve agriculture. Drought disasters, especially in the spring, are frequent occurrence in Hainan Island and such engineering measures as the construction of reservoirs are, therefore, necessary. To a certain extent, the water conservancy structures have benefited the people of the island. For example, there were only 12 thousand mu of rice paddies in Changjiang County in the beginning of the liberation when there was no such construction. The farmers there lived on sweet potatoes. Now that the water conservancy structures have been constructed, the area of paddies has been enlarged to 90 thousand mu; beyond the rice production, the problem of drinking water for the 150 thousand inhabitants is resolved as well. The situation of Dongfang County is similar. Judging from the

[continuation of ZHONGGUO LINYE No 6, 1982 pp 4-5]

concrete condition, the Qicha Commune, for example, was surrounded by lushly forested mountains in the beginning of the liberation. The rainfall was plentiful and the local Li and Miao nationalities fully utilized this superior condition to construct reservoirs and channels to build paddies. Every year, 1.60 million jin of grains have been contributed to the State by this commune. Since 1957, as the virgin forrests at the sources of water were continuously logged, the streams gradually dried out. In 1980, the wells of the 15 villages of that commune were dry and the 5,000 inhabitants had no drinking water to cause this rich commune to live off loans and relief money, and the 200 kw hydroelectric power station to stop generating power. The author cautions that whenever water conservancy structures, such as reservoirs, are constructed, forests on the slopes within 500 m of the reservoirs should be protected and logging should be absolutely forbidden. Forests beyond the 500 m limit can only be selectively logged. Forests that have already been destroyed should be quickly restored through active afforestation, if the water conservancy structures are to continue to serve agricultural production.

TITLE: "Weather and Climate in China, 1981"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 4, 10 Apr 82 pp12-13

ABSTRACT: In 1981, the rainfall in China was unevenly distributed. Compared with a normal year, the rainfall was distributed more to the west than to the east and damages from drought and flood were rather severe in some provinces. In most areas of China, the spring was warmer than usual in 1981 and the autumn colder. In the summer, the weather was very hot in parts of the country while cold temperature damages appeared in Heilongjiang. Following the above general descriptions of the weather in China in 1981, the paper provides some details under the following headings: (1) The rain was especially frequent in the western and the norther part of the Northeast of China during the summer to result in very severe flood damages in Sichuan basin, the southern part of Shaanxi, and the eastern part of Heilongjiang. (2) The spring rain was weaker than usual in the middle and lower reaches of Changjiang; the hot summer months were not as noticeable; and seemly endless rain occurred in the autumn. (3) Spring drought was rather severe in the North and scarcely any rain in the autumn. (4) Very hot weather appeared in North China, south of the Changjiang, and South China for short periods in the summer. (5)Low temerature appeared in Heilongjiang and in most regions of the country, sustained lower than usual temperature appeared. (6) There were frequent hails in the spring and the typhoons landed during concentrated periods and the end of typhoons came later than usual.

TITLE: "Yield Forecasting With Circulation Factors"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 4,10 Apr 82 pp18-19

ABSTRACT: Steyaert, L. T. 's paper "Atmospheric Pressure and Wheat Yield Modeling " in AGRICULTURAL METEOROLOGY (No 19, 1978) is cited to show the growing interest in the studies on the relationship between weather and atmospheric circulation and the yield of grains in typical grain producing regions, in recent years. The rich Taihu plain of China is a typical grain-producing region and an analysis and comparison of the weather and circulation patterns of years of bountiful and poor harvests of that region should be a worthwhile project. A formula was decided upon to define a bountiful year, using the sum of unit yields of the 3 crops of wheat, rice, and rice of that region as the index and the weather patterns and circulation characteristics of those years were compared with the other years. The years of 1953, 55, 58, 65, 66, 67, 72, 78, and 79 are bountiful years; 1950, 54, 57, 60, 61, 75, and 77 are poor years; the remaining years are ordinary years. With the data of the

[continuation of QIXIANG No 4, 1982 pp 18-19]

years of 1954-1973 as the basis, forecast equations were formulated to be used to forecast the years from 1974 to 1979 to verify the accuracy of the equations. Calculation with the equations indicates the years 1978, 79, and 81 to be bountiful, the years 1975. 77, and 80 to be poor, and the years 1974, and 76 to be ordinary. This finding confirms with the facts exactly.

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 4,10 Apr 82 pp24-25

ABSTRACT: Using the periodic weather chart produced by the Jiangsu Provincial Research Institute of Meteorology as the basis, the paper reports an analysis with the DJS-6 computer to create a method of short-term precipitation forecasting. The method was put to use throughout the year 1981. In terms of forecasting clear or rainy days during the months of Jun and Jul, the accuracy rate was 90 percent; in terms of forecasting the grade of rainfall (classifying rain into heavy, storm, and heavy storm) the accuracy rate was 68.6 percent. The computation equation, the selection of forecasting factors, and the method of day to day precipitation forecasting using the technique of fuzzy mathematics are explained.

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 4,10 Apr 82 pp 29-30

ABSTRACT: After typhoon No 14 of 1981 was formed in the afternoon of 27 Aug in the Pacific Ocean to the northwest of Guam, it moved steadily at a speed of 20 km/hour in the northwestern direction to reach the sea about 250 km to the southeast of Shanghai at the 02 hour on 1 Sep before gradually changing its direction. During the period of direction change, its speed is obviously reduced. Phenomena of stoppage and turn appeared in the morning of 1 Sep at a distance of about 200 km from Shanghai to cause a prolonged windstorm and high tidal waves to attack Shanghai. The authors used the 713 Radar equipment made in China to carry out some systematic studies of this typhoon. Many echo photos of 5-10-minute intervals were taken during the period of direction turning of the typhoon. Based upon these data, the hurricane zone of the typhoon and its principle of change, the echo structure in the vicinity of the eye, the whirling and deformation phenomena of the eye, and the indicative action of the echo phenomena with respect to the movement and the change of intensity of the typhoon are discussed. Finally, data of synchronized observations with a 5cm 713-Radar and a 10 cm 843-Radar are used for some comparative analyses.

ORG: Shanghai Research Institute of Plant Physiology, Chinese Academy of Sciences

TITLE: "Trends and Objectives of Plant Physiology"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 1-3

ABSTRACT: The relationship between plant physiology and agriculture and the problem of how plant physiology can serve agriculture were passionately discussed in the 60's. During the period of domination of the gang of four, the function of plant physiology in agriculture was repudiated and many plant physiology teaching and research offices were abolished and the researchers dismissed. This was a part and parcel of the gang's attack against science and culture, but the confusion thus created in terms of the field of plant physiology has not been completely dispelled to this day. The author, the Director of the Shanghai Research Institute of Plant Physiology, suggested that the subject of how plant physiology is to serve the 4 modernizations should be made a special subject of discussion in this issue of the journal, and wrote this paper to lead the discussion. In the paper, the author explains that among the many problems dealt with in plant physiology, which is a basic science, the 2 major problems are: the special structure and function of plants that are different from other organisms and how plant physiology is to serve agricultural production. In the long run, these should not be the only problems. For example, many books have been published to discuss ecological physiology, such as the Man and the Biosphere subject proposed by the United Nations organization. The most serious problem is pollution created by industrial waste water and gas, which is a part of the problem of environmental protection. The proposal of M. Calvin to use special plants to produce hydrocarbon fuel to resolve the problem of energy shortage is also briefly mentioned.

TITLE: "To Serve Agriculture is an Important Task of Plant Physiology"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 3-4

ABSTRACT: Citing the paper of YIN Hongzhang titled "General Condition of Plant Physiology in the USA--Report of a Visit" in which these who engage in teaching, research, and extension in the universities of the USA are described as so closely coordinated that the results of research are quickly experimented in farms and applied in practice, while problems of production serve as a feedback to promote plant physiology research, the author attempts to explain in the paper that such phenomena of production as cotton boll shedding, high yield physiology of rice and wheat, moisture physiology, respiration metabolism, material transfer, plant hormone, etc. are key subjects of research of plant physiology that have direct relationship with crop production. At present, the mystery of life should be investigated on the molecular level to produce some results, but on the other hand results of research in physiology should also be continuously expanded and applied in agricultural production. Perhaps, a field of applied plant physiology should be established to emphasize that portion of plant physiological research which is to serve agricultural production.

TITLE: "Comments on the Development of Plant Physiology in China"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 5-7

ABSTRACT: In recent years, many classical basic biological sciences, such as morphology, physiology, and toxology have not received much attention and it has even become difficult to carry out teaching and research work in these fields. The survival of these sciences has begun to be feared by many. The author claims in the paper that the future of plant physiology is really bright because it is the theoretical foundation of mankind's control of individual and colonies of plants. Undoubtedly, plant physiology will proceed deeper to the level of cells, subcells, and large molecules but the results of research on all these levels must be verified in the process of mankind's control of individual plants and plant colonies before they have practical value. With further readjustment of the national economy, there will be an urgent need of readjusting the biological sciences. First, the research work must be planned in accordance with the capability and whatever that is not urgently economically needed should be temporarily put off. The author suggests the following items: (1) Physiological analysis of high yield experiences; (2) Special research targets, such as legumes; (3) Physiological foundation of optimal cultivation systems; (4) Physiological action of organic fertilizers; (5) The physiology of distant hybridization.

TITLE: "Developing Plant Physiological Research Centering on Key Problems of Agricultural Production"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 7-8

ABSTRACT: Although plant physiology is a basic science to serve agricultural production, its importance and its place in agricultural production have not yet been given sufficient attention to this day. Under the new situation in the country, many natural sciences are facing serious challenges which will also have some effect on plant physiological research. On the basis of the author's many years of work in the field, he proposes the following viewpoints for open discussion of his colleagues: (1) Looking for research subjects in agricultural production practice; (2) Combining slow and protracted research subjects with some fast and quickly showing result subjects: Plant physiological research organizations have no centralized supervising structure neither do they have links with subordinate production departments, unlike plant breeding organizations. If the research projects all take years and years to show results, their very survival may be in doubt. Plant physiologists; therefore, should contact production departments to find short projects, such as using tissue culture to select early maturing Xian rice breeds, to gain support as well as income even if some manpower may have to be diverted from the long term projects.

TITLE: "How Can Plant Physiology Contribute to the Modernization of Agriculture?"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 8-9, 53

ABSTRACT: In terms of ways for plant physiology to serve agricultural production better, the author offers the following suggestions: (1) Among scientists and in the society there should be a better understanding of the interrelationship between plant physiology and agricultural production, including the understanding that result of basic theoretical research may not bring about immediate productive benefit, the interrelationship and its importance remain unchanged. (2) The teaching, research, and application of results of plant physiology must be linked with agricultural production; i.e. theory must be proved to be true or false through its application in production. (3) Training a staff for the agricultural and forestry departments with skills in plant physiology, including cell membrane and enzyme physiology, environmental protection physiology, applied physiology of hormones and vitamins, physiological and biochemical techniques of analyses, new instruments, etc.

TITLE: "A Study on the Isozymes of Haploid, Diploid, and Triploid Plants of Rice (Oryza sativa)"

SOURCE: Shanghai ZHIWU SHENGLIXUE TONGXUN [PLANT PHYSIOLOGY COMMUNICATIONS] in Chinese No 1, 20 Feb 82 pp 48-49

ABSTRACT: Haploid rice plants of relatively low vitality were obtained through anther culture and a large quantity of callus tissues were unable to become plants. The rate of success is generally even lower with Xian breeds. This phenomenon has been assumed to be caused by the unfavorable recessive gene expression following haploidy; therefore, attention is given to the study of gene function. Others believe it is caused by the culture condition and prefer to emphasize the study of the culture condition. For the purpose of clarifying the major cause of low vitality of haploid rice plants, the isozyme experiment is designed. Katayama et al have proved that haploids and quadruploids of the same breed have identical enzyme spectrum but they have not reported the isozymic expressions of haploids and diploids of the same breed. Results of the experiment indicate that the isozymic spectrum of all three is identical; the seeds of the triploid are obviously larger than those of the diploid but the fruiting rate of the former is extremely low. The vitality of the haploid and the diploid of the same gene type is obviously different and the difference is demonstrated in the size of plant, seed, and leaf. The author concludes that continuous study of the culture condition appears to be necessary.

TITLE: "Studies on the Rich White-winged Leafhopper in Hunan"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 83-87

TEXT OF ENGLISH ABSTRACT: The rice white-winged leafhopper, Erythroneura subrufa (Motschulsky), is an important pest of rice in south China. It also damages wheat in late autumn and early spring. In recent years, the insect population has tended to increase in the rice growing areas of south China.

This pest pierces rice leaves and sucks out the leaf juice and destroys the chlorophyll. When the rice leaves are seriously injured, many white streaks appear and the chlorophyll disappears. Finally the leaves dry up. Except for the black unispotted leafhopper, no leafhopper can cause rice leaves to show the symptom of small white spots.

The rice white-winged leafhopper has three generations per year. After the late rice is harvested, the adults move from paddy fields to wheat fields and weeds, and later hibernate there.

[Continuation of ZHIWU BAOHU XUEBAO No 2, 1982 pp 83-87]

The population dynamics of the rice white-winged leafhopper are closely related to the weather, farming system and cultural practices.

As for the chemical control of this pest, emphasis should be placed on the control of the hibernating insects in the wheat fields and the nurseries of early and medium rice.

TITLE: "Preliminary Study of Field Population of Pink Bollworm and the Effect of Insecticides"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 95-101

TEXT OF ENGLISH ABSTRACT: This article deals with the study of field population dynamics of Pectinophora gossypiella (Saunders) and the effect of application of insecticides on them during the period of 1977-1980.

The number of adults of the pink bollworm increased gradually from the first to third generations in the Shanghai suburbs, except in 1977, forming the third generation thriving patterns. The fluctuation of population of the adults and eggs in 1977 and 1980 was due to the weather during the ovipositing period.

The peak period of oviposition of the second and third generations occurred on 5-10 August and 5-10 September respectively. The degree of damage caused by the second and third generation larvae could be seen from the number of mature larvae per boll.

[Continuation of ZHIWU BAOHU XUEBAO No 2, 1982 pp 95-101]

The effect of insecticides applied to the pink bollworm was different due to different population densities. In years of light infestation, such as 1977, the number of larvae per boll was not significant between the treated and check plots or between the plots with one or four applications of insecticides. However in years of medium or serious investation, the density of larvae could be reduced more than 50 percent when the second and third generations were given one application each before the peak of oviposition.

Thus, the present study shows the possibility of reducing insecticide application in certain years.

TITLE: "Seed Borne by the Rice Leaf Blight Organism and Its Inspection"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 103-108

TEXT OF ENGLISH ABSTRACT: Results of experiments demonstrated that the bacterial leaf blight organism (Xanthomonas oryzae) of rice was present in the seed samples from diseased fields. A large amount of phage specific to the leaf blight organisms was also found in the infected seeds. Both the pathogenic organisms and the specific phage were present in the glume of the rice seeds, and large portions of the pathogenic organism were found to be lyzed by the phage. The longevity of the phage was much longer than that of the pathogen, but the rice leaf blight organism can also survive within the glumes for at least 6 months as one of the main sources of primary infection. The route of infection of the seed borne organisms causing the infection of the seedling is still waiting investigation. Due to the fact that both the causal organism and its specific phage could be detected only in rice seed samples from the diseased field, and none of them could

[Continuation of ZHIWU BAOHU XUEBAO No 2, 1982 pp 103-108]

be found in the seed samples from the diseased rice fields, three methods of inspection were used by applying the phage technique. The most simple and sensitive method is to detect and determine the number of phages in the glumes. Another method is based upon determining the number of living bacteria by counting the number of plaques formed by the phage-infected living bacteria. The presence of the causal organism in the seed sample can also be detected by determining the multiplication of the phage in the samples after incubation. Usually this method is not necessary for routine inspection. Some steps of these techniques can be simplified. We are trying to work out a more practical method to detect the multiplication of the phage in the seed samples.

TITLE: "Disinfection of the Rice Seeds Carrying the Bacterial Leaf Blight Organism"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 109-112

TEXT OF ENGLISH ABSTRACT: The phage-technique was applied to investigate the disinfecting effect of various treatments for killing the bacterial leaf blight organism (Xanthomonas oryzae) within the infected rice seeds. Among the treatments tested, the most promising were found to be dipping the rice seeds in a 0.5 percent solution of hydrochloric acid for 72 hours or in a solution containing 500 units of chloromycetin per milliliter for 48 hours. The phage technique is a reliable and accurate method for assaying antibiotics and other chemicals used to treat rice seeds for controlling the bacterial leaf blight.

TITLE: "Studies on the Control of Helminthosporium carbonum of Corn"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 113-118

TEXT OF ENGLISH ABSTRACT: Ji-63 is an important inbred line of corn in Jilin Province, but there has occurred an ear-decay disease which has caused heavy loss. The causal organism has been identified as Helminthosporium carbonum Ullstrup which infects the ears and leaves on corn. The morphology and culture characteristics of the pathogen are different from those of H. maydis.

Inoculation tests made at the seeding stage in the greenhouse and at the adult stage in the field revealed that H. carbonum can only infect the ears of the normal-cytoplasmic type Ji-63 and a few other lines, and not the T- and M-cytoplasmic type sterile and other normal lines.

[Continuation of ZHIWU BAOHU XUEBAO No 2, 1982 pp 113-118]

The prevalent period of infection is from the heading to milking stages. The pathogen is mainly overwintered in the residual tissues by mycelium.

Resistance of the 655 inbred lines and hybrids was estimated in the fields in 1976-1981. Ji-63 and its selective lines were susceptible.

TITLE: "Studies on Stem Blight Disease of Cotton in Shanghai"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 2, 1982 pp 119-124

TEXT OF ENGLISH ABSTRACT: Stem blight disease of cotton is an intermittent disease in Shanghai. The causal organism (Ascochyta gossypii Sadow.) of cotton stem blight can be cultivated on various media. The fungi grow over a wide pH range, with an optimum from 6.8 to 7.8. Best growth can be obtained on a culture medium containing a small quantity of sodium chloride (about 0.1 percent). A small amount of carbon source seems necessary for germination of the spores. The optimum temperature for spore germination ranges from 19.0-22.5°C for mycelium growth. With artificial inoculation on island cotton, the disease was developed at 23°C preferably, and the incubation period on island cotton was about 1 day shorter than that of upland cotton. Furthermore, on a plant with wounds, the incubation period was 1-2 days shorter than that of a plant without wounds.

The infected debris in the soil are considered the main source of primary infection of stem blight in cotton. The reinfection occurs due to pycnidiospore dispersed by

[Continuation of ZHIWU BAOHU XUEBAO No 2, 1982 pp 119-124]

wind and rain. Temperature, humidity and rainfall are the most important climatic factors, while cultural conditions may also considerably influence the development of the disease. Daconil is the most effective fungicide for controlling the disease.

TITLE: "The Direction and Major Responsibilities of Agricultural Science and Technology Extension Work"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 4, 5 Apr 82 pp 5-7

ABSTRACT: At present, a new tide of learning science and using science has emerged in most rural villages. This is an unprecedented situation, appearing only after the agricultural production responsibility system was established and perfected. Yet, the tendency of emphasizing research and neglecting extension exists still and should be earnestly corrected. The author maintains that the major tasks of science and technology extension work should be as follows: (1) The chief aim should be to increase the unit yield. The cultivated acreage can no longer be enlarged and diking the lakes to build new fields is no longer feasible. The direction is, therefore, to increase the unit yield and the past mistakes of compulsion and superficial adoption must be overcome in the extension work. (2) The work of extension must not be limited to increasing the quantity of agricultural by-products; efforts must be made to improve the quality of such products. (3) Finally, in the past, in agricultural production, the cost, the labor consumption, and the profit or loss were not calculated. Today, improving the economic benefits is the urgent subject, and the work of extension must include strengthening the business management, the economic accounting, and the financial system to reduce and eliminate unreasonable expenditure.

TITLE: "Several Opinions Concerning the Separation of Political and Commune Organizations"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 4, 5 Apr 82 pp 8-10

ABSTRACT: On 28 Feb, the news of the Second Conference of the Constitution Revision Committee appeared in the RENMIN RIBAO. In the paper, the 2 questions of whether in the revised constitution the political and the commune organizations should be separated and if the people of the country should select to separate the two what forms of political authority and economic authority in the rural villages are reasonable were brought up. The cadres and masses of rural villages are very concerned about the 2 questions. Various contradicting ideas are introduced in the paper. The paper concludes that: (1) The basic accounting unit must be kept stable; (2) The present rights of properties of the communes and the brigades must not be destroyed. (3) The form of the economic organization must be democratically decided by the members. (4) The work must not be adversely affected. (5) Rural cadres must be satisfactorily arranged.

TITLE: "On the Road of Primarily Organic Agriculture"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 4, 5 Apr 82 pp 12-13

ABSTRACT: In Oct 81, the author participated in the Second International Conference of Intensive Agriculture held in the USA. He was impressed by the attention of the delegates of many countries with respect to the traditional experience of agricultural production in China. Many asked him to tell the ways of making farm compost fertilizer, ways of achieving a unity between cultivating and nurturing the land, and ways of resolving the problem of food supply under the condition of a little over one mu of cultivated land per capita, etc. Many specialists of developed countries lamented their negligence of organic farming to result in applying too much chemical fertilizer, insecticides, herbicides, and other industrial substances into the land to cause environmental pollution in the process of agricultural production. This conference inspired the author to write this paper to praise the organic farming tradition of China. He claims that the way to develop organic farming is; (1) To emphasize farm fertilizer accumulation; (2) To plant crops suitable for the land, to rotate the crops, and to turn over the stubble; (3) To improve the level of science and technology of the farmers and the basic level cadres.

TITLE: "Helping the Contracting Households To Raise the Economic Benefits"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 4, 5 Apr 82 pp 23-24

ABSTRACT: The department carried out a survey of 100 households of 83 production teams of 49 production brigades of 18 communes. Of these households, 26 belong to teams practicing the system of linking production and labor consumption while 74 households belong to teams practicing contract work. Under almost identical conditions, the economic benefits of the 100 households varied a great deal; with the average per capital income of 477.12 yuan, 12 percent of the households had per capita income of above 1000.00 yuan while 22 percent had a per capita income of below 200 yuan. The reasons for the difference appear to be (1) Extensive and reasonable use of labor; (2) Level of science and technology; (3) Full utilization of land; (4) Production cost and expenditure. Ways of helping those households of low per capita income to overcome these problems are detailed.

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 2, 20 Feb 82 pp 14-17

ABSTRACT: From the middle of Nov 79 to Apr 80, there was an epidemic of "festered foot disease" among the farm cattle, mainly water buffalos, in Zunyi Prefecture. Of the 152 production teams of the 68 communes, of the 33 districts and 8 counties (municipalities) of the prefecture, there were a total of 1,033 cases and 271 died of the disease. The symptoms started with lameness and progressed into swollen legs, festering, cracked hoofs (falling off in some cases) and necrosis of the tips of ears and tails. Following analyses of blood, feces and microbiological and parasitological examinations, as well as feeding experiments, it was tentatively diagnosed to be the result of being fed with moldy straw. Results of chemical analyses and pathological examinations are reported.

TITLE: "A Survey and Research of Swine Toxoplasmosis in Henan Province"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 3, 20 Mar 82 pp 4-7

ABSTRACT: For the purpose of clarifying the existence and the extent of damage of swine toxoplasmosis in Henan Province, the authors carried out an epidemiological survey, a pathogen isolation project, a serological diagnosis project, a morphological observation of the parasite bred in mice, and a project of reinfesting pigs with offsprings of parasites bred in mice. Herds of pigs in Zhengzhou, Nanyang, Xuchang, and Xinxiang were involved in the study. From late Feb to early Mar, high fever of unknown origin was discovered among pigs in the suburb of Zhengzhou and application of various antibiotics produced no effect. The blood and lymph node of one pig were analyzed and Toxoplasma was isolated. The incidence of the disease rose rapidly in Jul, Aug, and Sep, to a rate of 16-49 percent, and the mortality rate of the infested pigs was 30-66 percent, mostly among pigs weighing 30-100 jin. The clinical symptoms, the pathological signs, and the treatment and prevention measures are also reported with the results of morphological observation and experiment using mice.

TITLE: "Treatment of Schistosoma japonicum Infestation in Farm Cattle With Nithiocyanamin"

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] in Chinese No 4, Apr 82 pp 2-5

ABSTRACT: Nithiocyanamin is an antischistosomiasis compound containing no antimony. It was synthesized in foreign countries in the early 70's and has been applied for experimental treatment for various types of schistosomiasis. There are no reports of its use in veterinary medicine, however. Begining in Oct 75, the authors have experimented with this drug made in China in various forms, administration, dosages, and treatment durations to test the effects on sick farm cattle of artificially induced and natural schistosomiasis japonicum. Judging from the results of 35,787 test cases, one intravenous injection of 2 percent nithiocyanamin in water suspension is the most satisfactory. The dose for water buffalos should be 1.5 mg/kg and it should be 2 mg/kg for yellow oxen. Procedures and results of the various experiments are reported.

TITLE: "Genesis, Classification, and Utilization of Taigu Sterile Wheat"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 6, 20 Jun 82 pp 9-13

ABSTRACT: A sterile wheat was discovered in Taigu of Shanxi Province in 1972. It has many obvious special characteristics, compared with all the other sterile wheat plants discovered previously here and abroad and many papers have been published on the subject. Instead of comparing, this paper attempts to present an analysis of its genesis and classification for the purpose of proposing ways of utilizing it. The 8 parents of Taigu sterile wheat are all common cultivated wheat breeds, and the sterile characteristic cannot possibly be the result of interaction between abnormal cytoplasm and normal nuclear gene. It is possible that one or more of the 8 parents has a single recessive sterile nuclear gene but through the action of its own restraining gene or genes, the sterility is not expressed. It is not until after several crosses before the restraining action is finally removed to produce the sterile plant. If the number of the restraining genes is few, some sterile plants should continue to emerge; if the number is numerous, the ratio of sterile plants of the F_1 of the fertile sister lines with the sterile line would be too complex to remain constantly at 1 : 1. In reality, a single sterile plant appeared in the 6th generation and when more than 200 sister plants were used by the Research Institute of

[continuation of SHANXI NONGYE KEXUE No 6, 1982 pp 9-13]

Atomic Energy Utilization of Chinese Academy of Agricultural Sciences to cross with the sterile plant, the ratio of sterile offsprings remained 1 : 1. The paper, therefore, concludes that it is not possible for any of the 8 parents to have a dominant sterile gene. The paper proceeds to examine the mutant nature of the dominant nuclear sterility of Taigu wheat. A sterile-free line for Taigu sterile wheat is, therefore, very difficult to find and as there is no complete restorer line, Taigu sterile wheat is not useful for heterosis utilization. Citing the experiences of C. Suneson of the USA and C. Driscoll of Australia, the paper proposes its utilization in breeding new varieties of wheat.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

I. GENERAL INFORMATION

COTTON PROCUREMENT REACHES ALL-TIME HIGH

Jinan DAZHONG RIBAO in Chinese 26 Jun 82 p 1

[Article: "1981 National Cotton Procurement at More Than 57 Million Dan. Cotton Procurement in Shandong at More Than 13 Million Dan, a More Than 2.5 Million Dan Increase Over 1980"]

[Text] The correspondent has learned from the national conference on cotton and hemp procurement, inspection and processing work convened today that as of the end of May, 57 million dan of the cotton procurement quota for 1981 (from September 1981 to August 1982) had been fulfilled, with 4 million dan more procured than in 1980 to create an all-time high for cotton procurement since the founding of the People's Republic. These figures include a more than 13 million dan cotton procurement in Shandong Province, which was 2.5 million dan more than in 1980, and a more than 11 million dan procurement in Jiangsu, which was somewhat more than 2.8 million dan more than in 1980. Anhui, Hebei, Henan, Xinjiang, Liaoning, Hunan, and Jiangxi provinces all overfulfilled cotton procurement plans.

Increase in the quantity of cotton procured has provided ample raw materials for the country's cotton textile industries, and goes a long way toward ameliorating the cotton supply shortage and satisfying the needs of production in the light and textile industries. National cotton reserves were 22 percent greater in 1981 than in 1979 for a corresponding decrease in cotton imports. In 1980 cotton imports were 11 percent less than in the previous year, and in 1981, they fell by another 32 percent over the previous year.

SAFETY REGULATIONS FOR PESTICIDES ISSUED

Nanjing XINHUA RIBAO in Chinese 11 Jul 82 p 2

[Article: "Strictly Carry Out Regulations For Safe Use of Pesticides"]

> [Text] Editor's Note. During the years there have been many accidental deaths from pesticide poisoning. This is attributable largely to failure on the part of many communes and brigades to "centralize" pest eradication work, and to allowing individual households to buy, store, and use pesticides following institution of responsibility systems linking output to individual laborers.
>
> We have already entered the season when large quantitities of pesticides are used to control diseases and insect pests, and we should genuinely strengthen leadership in safe use of pesticides, institute a comprehensive one time check production team by production team, and institute concrete measures. In order that the broad masses of grassroots level cadres, commune members, and those specializing in pest control will be able to master knowledge about the safe use of pesticides, specially reprinted here are "Safety Regulations For the Use of Pesticides," published by the Ministry of Agriculture, Animal Husbandry, and Fisheries, and the Ministry of Public Health. It is hoped that all jurisdictions will conscientiously carry out these regulations to assure the health and safety of the masses of people.

Safety Regulations For the Use of Pesticides

Use of chemical pesticides to prevent and control diseases, insect pests, weeds, and rats is an important measure in winning bumper agricultural harvests. But unless used properly, they can pollute the environment and agricultural and livestock products, poison people and livestock, or cause death. In order to assure their safe production, the following regulations have been drawn up:

I. Pesticide Classification

On the basis of an overall appraisal of toxicity (acute ingestion, poisoning through the skin, and chronic poisoning), common pesticides currently produced have been classified as being of high toxicity, moderate toxicity, and low toxicity.

1. Pesticides of High Toxicity: American Cyanamid 3911, suhua [5685 0553], parathion, parathion methyl, demeton, shamingwei [3010 5820 1218], monocrotophos, phosphamidon, methamidophos, yibinglin [3976 0014 4340], carbophenothion, omethoate, zinc phosphide, aluminum phosphide, cyanide, furanose, fluoroacetanilide, diarsenci trioxide, shachongmi [3010 5849 518B], ethulmercury-chloride, Ceresan, kueiyangjing [3391 4046 0403], chloropicrin, pentachlorophenol, ethylene dibromide, and 401.

2. Pesticides of Moderate Toxicity: sumithion, dimethoate, phenthoate, ethion, imidan, piyinglin [4122 5859 4340], benzene hexachloride, lindane, toxaphene, chlordane, DDT, carbaryl, haipuwei [1365 2333 1218], MIPC, tsumacide, hunmiewei [3236 3528 1218], pirimicarb, fenthion, dichlorvos, juzhi [5468 7927] types intended for the eradication of insects, edinphensoph, EBP, dikesong [2420 0460 2646], 402, asomate, daojiaoqing [4470 5183 7230], tuijunte [6622 5497 3676], ambam, milneb, yanmaidi [3601 7796 2420], 2-4 D, and qingcaoan [3021 5430 5143].

3. Pesticides of Low Toxicity. trichlorfon, malathion, acephate, phoxim, tetradifon, carbendaxol, triophanate, captan, zineb, thiram, weixiuling [5494 6907 7227], IBP , Yilinlu [0044 1340 6986], chlorothalonil, nitrofen, propanil, atelajin [7093 3676 2139 3160], butachlor, lasu [2139 4790], benthiocarb, MCPA, lumailong [4845 7796 7127], diuron, trifluralin, bendasong [0058 6671 2646], dichloropropionic acid, and Hercules.

Contact with only extremely small quantities of high toxic pesticides can cause poisoning or death. Though pesticides of moderate and low toxicity are less toxic than highly toxic pesticides; nevertheless, unless rescue in time after sustained contact, death can result. Thus, when using pesticides, one must practice economy and safety.

II. Scope of Pesticide Use

All varieties for which "Pesticide Safe Use Standards" have been formulated should be used in accordance with the "standards." For varieties for which no "standards" have as yet been formulated, the following rules should be followed:

1. Pesticides of High Toxicity: Not to be used on vegetables, tea, fruit trees, or traditional Chinese medicinal plants. Not to be used for the prevention and control of insects that are injurious to public health or on skin diseases of people or livestock. Not to be used to poison rats except in rat poisons. Fluoroacetanilide is prohibited for use on farm crops and may not be used to kill rats. American cyanamide 3911 emulsion may be used only for

disinfection of seeds; it is prohibited from use as a spray. Furanose pellets may be used only for disinfecting seeds, or may be used to disinfect the soil either by being put into furrows with a tool or spread with a gloved hand; it may not be mixed with water and sprayed.

2. Pesticides of High Residual Toxicity: benzene hexachloride, DDT, and chlordane may not be used on fruit trees, vegetables, tea shrubs, Chinese medicinal plants, tobacco, coffee, pepper, or lemongrass. Chlordane may be used only for disinfecting seeds and for prevention and control of injurious subterranean insects.

Chlorophenamidine. May be used in prevention and control of red spiders on cotton and for paddy rice borers. Research results on chlorophenamidine toxicity show that its use should be controlled. It may be used only once throughout the entire period of rice growth. When 2-liang (100 grams) of Chlorophenamidine per mu in a 25-percent water solution is used, it may not be applied less than 40 days from the harvest; when 4 liang (200 grams) of Chlorophenamidine per mu in a 25-percent water solution is used, it may not be applied any less than 70 days before the harvest. It is forbidden for use on other goods, edible oil crops, vegetables, fruit trees, Chinese medicinal plants, tea, tobacco, sugarcane, or sugar beets. When used for the prevention and control of insect pests of cotton, utmost control should be exercised in the number of times and amounts used. When sprayed, direct contact between the solution and the human body are to be avoided.

3. It is forbidden to use pesticides to poison fish, shrimp, frogs, and beneficial birds.

III. Purchase, Transportation and Storage of Pesticides

1. Pesticides are to be purchased by user unit designated persons holding certificates. When buying pesticides, attention must be given to their packaging to prevent breaks and leaks. Attention is to be given the name of the item, content of effective ingredients, the ex-factory date, and instructions for use. Insecticides the uses for which are uncertain and those that have lost effectiveness may not be used.

2. In transporting pesticides, one should first check the packaging to make sure it is intact. If any leaks or breaks are discovered, the insecticide should be repackaged using designated material after which it may be transported. Ground, transportation vehicles or packaging materials that have been contaminated should be properly and promptly handled. When moving pesticides, they should be handled gently.

3. Pesticides should not be carried or placed together with grain, vegetables, melons and fruits, foodstuffs, or items used in daily life.

4. Pesticides should be stored centrally in special warehouses or special chests in production teams, work teams, or specialized work units, and be looked after by designated persons. They may not be stored in individual

households. Doors and windows should be secure; ventilation conditions should be good; and doors and chests should be locked.

5. A registration procedure should be established for taking pesticides into or out of warehouses. They may not be arbitrarily deposited or removed.

IV. Matters To Be Given Attention in Using Pesticides

1. When compounding pesticides, those involved are to wear rubber gloves, and they must use measuring instruments to weigh out the specific amount of solution or powder. They may not arbitrarily increase amounts used. Mixing of pesticides with the hands is strictly forbidden.

2. When disinfecting seeds, a tool must be used for mixing. The amount of mixing done depending on the amount of pesticide being used. Disinfected seeds must, to the maximum extent possible, be sown by machines. If spread by hand or dibbled, protective gloves must be used in order to prevent absorbing the poisons. Toxic seeds left over are to be destroyed; they may not be used either for human consumption or for animal feed.

3. Compounding of pesticides or disinfection of seeds should be carried out at a safe place distant from sources of drinking water and residential sites. A person is to be designated to be in charge to make sure that pesticides or toxic seeds are not lost or mistakenly eaten by people, livestock, or domestic fowl.

4. When using hand powered spraying devices, spraying should be done one row distant. Hand operated or power driven pesticide devices should not be used to spray from both the left and the right side at the same time. Spraying with pesticides should be stopped during high winds or during high noon temperatures. One should not overfill pesticide containers so pesticide will not slop out, contaminating the bodies of those applying the pesticide.

5. Before beginning spraying, openings of pesticide devices should be carefully inspected as should all connections, and the spraying head to make sure that screws are tight and that there are no leaks in containers to avoid contaminating pesticide leaks. If, while spraying pesticide, any stoppages occur, the equipment should first be flushed with clear water after which the obstruction can be removed. It is positively forbidden to use the mouth to blow or suck the spray head and filtering screens.

6. Places using pesticides of overly high toxicity should set up standards, prohibiting at certain fixed times the pasturing of livestock, the cutting of hay, and the digging of edible wild herbs to prevent people or livestock from being poisoned.

7. After pesticide use has been completed, spraying equipment should be thoroughly washed, and returned together with any left over pesticide mixture to the warehouse for storage. It may not be taken home. The wash water used to clean the pesticide equipment should be properly disposed of in a safe

place. It should not be poured any place on the ground so as to prevent pollution of sources of drinking water and ponds used for the raising of fish. Pesticide containers may not be used to hold grain, edible oil, wine, or water. Empty pesticide boxes, bottles, and bags are to be centrally handled. Containers used to disinfect seeds should be thoroughly washed and stored in a centrally supervised place.

V. Selection of Pesticide Personnel and Individual Protection

1. Production teams should select as pesticide personnel young able-bodied men in good health who are responsible, and they should receive a certain amount of technical training.

2. Those who are weak in body and frequently ill, those suffering from skin ailments and those who have not yet recovered health after having been poisoned by pesticides or having been otherwise ill, women who are nursing, are pregnant, or are menstruating, and those with as yet unhealed skin wounds should not spray pesticides or should temporarily halt spraying pesticides. Children are not to be taken to work sites at the time of spraying.

3. Pesticide personnel are not to drink alcoholic beverages during the period when pesticides are being applied.

4. When applying pesticides, pesticide personnel must wear protective masks over their mouths, wear long sleeved clothing, trousers, socks, and shoes. When at work, smoking, drinking water, and eating is forbidden, and hands are not to be used to wipe the mouth, face, or eyes. Horseplay involving spraying one another is positively not permitted. After work, before drinking, smoking, or eating, the hands and face should be thoroughly washed with soap and the mouth washed out. Where conditions permit, a bath should be taken. Work clothing contaminated with pesticide should be promptly changed and washed.

5. Pesticide personnel should usually not spray for more than 6 hours a day. Two people should take turns operating machine operated spraying equipment carried on the back. After spraying pesticide from 3 to 5 days, 1 day of rest should be taken.

6. Should operators get a headache, dizziness, nausea, or vomit, they should leave the spraying site at once, take off their contiminated clothing, rinse their mouths, wash their hands, face, skin, and such exposed parts, and be sent promptly to a hospital for treatment.

IMPORT OF AGRICULTURAL SCIENCE, TECHNOLOGY IN NATIONAL ECONOMY

Tianjin KEXUEXUE YU KEXUE JISHU GUANLI [SCIENOLOGY AND THE MANAGEMENT OF SCIENCE AND TECHNOLOGY] in Chinese No 3, 1982 pp 35-36

[Article by Xin Naiquan [0207 6621 6112], Research Managment Department, Chinese Academy of Agricultural Sciences: "Agricultural Science and Technology Has Become a Productive Force of Ever Increasing Importance"]

[Text] Agriculture is the foundation of the national economy. Growth of agriculture depends on policies first and on science second. Agricultural science and technology must adhere to a program of serving agricultural production to give impetus to the high speed development of agricultural production. This is a major issue that bears on the building of modern agriculture as a whole and on the future of the building of socialism.

Science and technology is a productive force not only in industry but in agriculture as well:

1. Development of genetic theories and breakthroughs in breeding techniques have increased farm crop output tremendously. In 1918, American scientists bred hybrid corn, which began to be extended to cultivation during the 1920's. During the 1940's and the 1960's the speed of increased yields was a general 100 jin per mu every 10 years, and during the 1960's and 1970's, the speed of increase in yields was almost 200 jin per mu every 10 years. In 1979 more than 400 million mu were planted producing average yields of 915 jin per mu. Statistics show that among the major factors in increased corn yields, hybrids accounted for between 40 and 50 percent. After corn and gaoliang, breakthroughs in China's hybrid rice produced new takeoffs in output. The coherent matching of "three lines" was achieved in 1975, and in 1976 hybrids were extended to wide area cultivation. By 1980 the five year accumulated area of cultivation amounted to more than 250 million mu, and paddy output increased to more than 26 billion jin or more than 2.6 million renminbi in money terms. Not only did hybrid rice produce tremendous economic benefits within the country, but it is in process of moving forward in some of the countries of the world. In 1977, test plantings succeeded in Kampuchea, and in 1979 the Philippine International Rice Institute did test plantings. In 1980 China's first patent on agricultural technology was transferred to the United States where direct cuttage [4160 8422] experiments with five combinations have been conducted resulting in 1.6 to 1.8 fold yield increases as compared with local fine varieties.

2. Development of Farmland Water Conservancy and Biology Have Blazed a New Trail for Improvement of Low Yield Fields. China's plains of the Huang and the Huai have long been areas of numerous disasters and low yields. During recent years, as a result of investigation and study, a system has been worked out that uses deep ditches and a combination of lifting water for drainage and lifting water for irrigation, a combination of well irrigation and ditch irrigation, and a combination of extracting and using saline river irrigation with ditch drainage to provide scientific evidence for comprehensive control of drought, waterlogging, alkalinity, and infertility. Right now in the Lingxian and Yucheng experimental areas alone, this system is used on 150,000 mu, and the area on which it is being demonstrated and promoted amounts to 3 million mu. Grain yields per unit of area have increased from the 180 to 200 jin before control to between 465 and 513 jin. Cotton yields have increased from the former 84.5 jin to 192.5 jin. In the Lingxian experimental area, average commune member earnings increased from 54.10 yuan per capita in 1975 to 132.40 yuan. In the Yucheng experimental area, commune member per capita earnings decreased from 40.70 yuan in 1975 to 96.50 yuan in an initial change in the situation of many disasters and low yields. The red and yellow soil hills and mountain lands in South China, which are found over a wide area, are China's major soil resource. Adaptation of general methods to local situations for comprehensive control has won remarkable results during the past several years, and a group of grain, oil, and sugar production bases have been established to make a contribution to the country.

3. Development of Plant Protection Science and Chemistry Has Effectively Reduced and Controlled Diseases and Insect Pests, Has Reduced Losses, and Has Increased Output. Locusts have plagued China throughout history. Since the founding of the People's Republic great results have been scored through the organization of researchers to go into locust areas to investigate and study, and to summarize experiences. Incomplete statistics show a former locust area nationally of somewhat more than 60 million mu, which has now been reduced to somewhat more than 14 million mu. Between 1956 and 1965 more than 30 billion jin of grain was saved thereby. Rust is China's most serious wheat disease. In 1950 it was prevalent throughout the country reducing output by more than 12 billion jin. In 1964 it again caused damage over an area of 120 million mu. In Hebei, Shandong, Jiangsu, Shaanxi, Shanxi, Gansu, and Beijing alone, it reduced yields by more than 2 billion jin. In 1965, with the loving concern of Premier Zhou, the State Council approved a national cooperative program for the eradication of wheat rust, further intensified scientific research, and put forward a comprehensive policy of prevention and control of "taking disease resistant varieties as the key supported by chemical prevention and control and farming methods." Since 1965 damage resulting from epidemics of wheat rust has been substantially controlled for an annual wheat saving of more than 2 billion jin, which converts to 250 million renminbi.

4. Growth of Animal Husbandry Science and Livestock Feeding Science Has Doubled the Return on Livestock Feed and Greatly Shortened the Feeding Cycle. Hybrid heterosis has been widely applied to chickens, hogs, and cattle. In the United States in 1956 hybrid chickens accounted for 73.4 percent of those sold; in Japan in 1969, it was 76 percent; in Canada the finest eggs came from

hybrid chickens, each hen laying 258 eggs each year, each egg weighing 61.3 grams, with a feed consumption rate of 2.45. Breeding has produced remarkable successes in hog quality. Danish "Landraces" are a world famous bacon type hog variety characterized by much lean meat and an average daily weight increase of from 623 to 737 grams, and for which the feed consumption per kilogram of weight gain has been reduced from 3.76 kilograms to 2.93 kilograms. In California, American buffaloes have been crossed with beef cattle to breed a new variety of beef cattle called "beefaloes." In the course of a 8 to 10 month period of grass pasturage, body weight reaches 454 kilograms; meat quality is good and production costs are low. As a result of innovations in power and machinery science and technology, in particular, the mechanization and factorization of chicken, hog, and cattle raising have developed very rapidly, tremendously increasing labor productivity rates. Under conditions of factorized feeding, at 8 months meat chickens weigh 2 kilograms; at 6 months fattened hogs weigh between 90 and 100 kilograms; and high producing milk cow herds average 8,000 to 9,000 kilograms of milk per cow annually.

One can see clearly from all this the role of agricultural science and technology. Agricultural science and technology as a productive force will certainly more and more demonstrate its tremendous power. However, our understanding of the productivity of agricultural science in the practice of production is very inadequate and the pernicious influence of it being "all right to have or not to have" is rather serious. For this reason, it is necessary to hasten the pace of agricultural science and technology so that scientific research will be in the forefront of the building of production, and science and technology applied to increase labor productivity and the development of agricultural production. This is a key measure in educating and leading the broad masses to bring about the modernization of agriculture.

If agricultural science is to be in the forefront of the building of production, it is necessary, first of all, to provide agricultural production with the fruits of science and technology. The new tasks and new problems that development of agricultural production raises require that we study and explore, on the basis of the objective laws of agricultural production, the various possible problems that can crop up in each stage of development the better to prepare promptly ways and means of solving them, and to increase scientific and technical reserves. Such an anticipatory development of scientific research can make the most of the tremendous role of agricultural science and technology in guiding production and in giving impetus to production.

If agricultural science and technology is to be in the forefront of the building of production, it is also necessary to steadily pioneer new fields of science and technology, to fill in gaps, and to strengthen weak links. Because of the permeation of modern mathematics, physics, chemistry, and biology, profound changes have occurred in agricultural science and new leaps have occurred. Examples include use of atomic energy and computer technology achievements to study the application to agriculture of research on isotope and nuclear technology and electronic computers. Since the 1970's, the United States has used remote sensing technology to observe from earth resource satellites the earth's soils, changes in fertility, changes in readication and spread of diseases and insect pests, drought and flood disasters and agricultural crop output forecasts in an extremely broad field of applications. In the past the United Kingdom conducted several soil utilization surveys, each time mobilizing 6,000 people to work steadily for 6 years. In 1976, they conducted their fourth survey using data from earth resource satellites using only four people and 9 months' time to complete the job, which was several times better. All these things have meant extremely tremendous progress for agricultural production and techniques. New developments in modern science and technology are occurring at an unprecedented pace and scope, and their application to agricultural production is promoting the modernization of agriculture.

If agricultural science is to be in the forefront of the building of production, it is necessary to vigorously intensify application of basic research. Back in the 1950's, Premier Zhou reminded us that "If we do not promptly devote more attention to long range needs and theoretical work, we will make a very great mistake. Without a certain amount of research in theoretical science as a foundation, there can be no fundamental progress or innovation in technology." Application to agricultural science of basic research depends on development of social productivity and the application of newly emerging technology. It is, in addition, the leading edge of all agricultural science and technology. Consequently, vigorous intensification of the application of basic research such as investigation of soil, water, and agricultural climate resources and agricultural crop, livestock and poultry variety resources, as well as genetic breeding, and the physiological ecology; application of basic research of major significance for agricultural science and agricultural technology such as genetic engineering, photosynthesis, the fixing of nitrogen by plants, and resistance mechanisms also require active research and exploration. Even if it is difficult to see for the time being the actual uses to which basic research can be applied, where conditions permit, appropriate resources should be devoted to it. Only when attention is given the application of basic research and there are abundant scientific reserves can impetus be given the development of all agricultural science and technology to spur on major technical innovations or even a technical revolution.

Since the Third Plenary Session of the 11th Party Central Committee, the situation on the agricultural science and technology front has been very good. Under the leadership of the CCP Central Committee, we must do all around planning, equitably distribute, readjust and restructure the agricultural research system, revive and perfect the system of promoting agricultural technology, take vigorous action to hasten the building of an agricultural science and technology corps, gradually improve conditions for research work, install the required instruments and equipment, and upgrade agricultural science and technology with all possible speed so that agricultural research will be in the forefront of the building of production, making new contributions to realization of agricultural modernization.

NEW TASKS IN DEVELOPMENT OF FARM MACHINERY OUTLINED

Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 1, 1982 pp 1-6

[Article by Hua Guozhu [5478 0948 2691], Chinese Academy of Agricultural Mechanization Sciences: "New Tasks in the Development of Agricultural Machinery"]

[Excerpts] (Summary) This article analyzes the new requirements in all around development of the mechanization of agriculture in the new situation of development of China's agricultural economy. The article presents some ideas about research tasks and improvements in research organizations for agricultural mechanization, the design and manufacture of new farm machines, for new sources of energy for agricultural use, and for improving quality of research personnel and strengthening management of research.

Research and development work is rooted in the needs of the development of production and in service to economic development. During the past more than 30 years, agricultural machinery developmental work has gradually developed in accordance with needs for development of agricultural production, for supplementing old farm implements, promoting new farm implements and actively carrying out the mechanization of agriculture, for improving old farm implements, for introducing, experimenting with, designing, and promoting new farm implements pulled by animals, for copying, and for improving and manufacturing mechanized farm implements, with many achievements having been made. Today China has more than 200 million horsepower of electro-mechanical power, and about 2,000 mechanized implements of various kinds, specifications, and models for farm and pastoral use. These are in use in all areas of agricultural production where they increase the capabilities of agricultural labor, decrease damage to agriculture caused by natural disasters, promote the carrying out of measures for increased production by the farming and livestock industries and their completion on time, and play a major role in increased agricultural production and earnings, increased peasant income, and development of the agricultural economy.

Despite waterlogging in the south and drought in the north during 1980 such as has rarely occurred in several decades, a bumper harvest was won in agriculture. Grain output totaled 636.44 billion jin, making it the second highest year for output, second only to 1979, since founding of the People's

Republic. Outputs of cotton, oil-bearing crops, sugarcane, sugar beets, jute, ambari hemp, silkworm cocoons, and tea all reached all-time highs. Substantial increase occurred in livestock production, output of pork, beef, mutton and goat totaling 24.19 billion jin, a 13.5 percent increase over 1979. Fairly rapid development also took place in rural commune and brigade economic diversification and in commune family sideline occupations. Gross earnings for the country's commune and brigade enterprises totaled 61.4 billion yuan, a 22 percent increase over the previous year.

As a result of increased agricultural production, a prise rise for the principle agricultural products, and development of commune household sideline occupations, peasant income increased strikingly. Data from the State Statistic Bureau show that during the past 3 years peasant income from the sale of commodities and from other labor or service activities has increased by a total of 31.04 billion yuan. Accompanying increase in peasant income has been a corresponding improvement in their livelihood. During 1980 more dwellings were constructed in rural areas than in any of the past 30 years.

As a result of rural economic development and readjustment of the structure of agricultural production, the peasants have raised new demands for the mechanization of agriculture. As peasant incomes have increased, the ability to buy farm machines has risen. In 1980 total personal outlays by commune and brigade peasants to buy machinery were greater than in 1979. Most rural areas practiced the contracting of production or work tasks to individual households with a curtailment of the scale of farming and the size of some field plots becoming smaller, purchases of farm implements being done by individual households or an association of households (a new collective economic body). Thus need for low power farm implements with associated equipment, hand tractors, animal-drawn carts, small water pumps, spraying machines, threshers, rice flour processing machines and grinding machines has increased. In a small number of areas where production levels are fairly high and collective farming is done, there is continued need for development of large and medium size farm machines, which places higher demands on farm implements. In the case of planting machines, for example, the need is for both precision and semi-precision machines. Threshing machines that simultaneously clean the grain are wanted, and combines are wanted for harvesting. Dryers are needed for grain, tea, tobacco and tremella, but since water content and drying requirements differ for various things, drying machines must be of diverse kinds.

In equitable readjustment of the structure of agricultural production and of crop patterns there will be improvement in the growing of grain crops to increase yields per unit of area, and there will be all-around development of economic crops and of forestry, livestock raising, sideline occupations, and fisheries. In the development of agriculture, there will be an adaptation of general methods to local situations for a strengthening of both biological and engineering measures. Accompanying increase in agricultural products will come an increase in the amount of transportation, processing, storage, and marketing. Increase in avenues of agricultural production will mean greatly increased demand for varieties of farm implements.

Expansion of peasant self-determination in production also entails deciding for themselves the farm implements to be selected. The peasants not only demand farm implements that work well and meet agricultural production needs, but also demand good quality, durability and dependability, and low prices so that after using the farm implements they will be able to derive greater economic benefits.

From this may be seen that the new situation in development of the agricultural economy has brought about new changes in requirements for the mechanization of agriculture. With the development of agricultural production and the passage of time, agricultural mechanization will enter a new era of all-around development. Agricultural mechanization will change from primarily serving grain farming to serving development of all of large scale agriculture, and the farm machine industry will be required not only to provide implements for consistently high grain output, but will also be required to serve development of economic crops such as cotton, edible oil, sugar and tea, the development of forestry, livestock raising, sideline occupations and fisheries, and serve the building of agricultural bases and improvement of peasant livelihood. The farm machine industry will have to provide diverse kinds of implements and equipment for farm use. Agricultural mechanization will gradually change from the basic mechanization stage, with mechanization of several major operations, to all-around mechanization with the use of machines in all the places and all the units in which machines can be used. This is an objective law that cannot be changed by people's wills. The laws of development of agricultural mechanization in foreign countries have been like this, and the laws of development of agricultural mechanization in China will also be like this. Naturally, in individual areas or individual production units there will also be the problem of how to go about mechanization, i.e., what to mechanize first and what to mechanize last. Formerly mechanization was begun with things urgently requiring action or with key projects, but now selective mechanization has to be done. Projects for mechanization have to develop from the few to the many; machine techniques must proceed from the simple to the complex; and the extent of mechanization must go from low to high. For the country as a whole, very great increase will take place in what is mechanized, and in the kinds and specifications of farm implements. Nevertheless, the extent of mechanization and quantities of machines required will depend on development of the rural economy, on changes in agricultural work forces, and on the ability of the state to supply energy and provide equipment and support funds for gradual development.

2

Scientific research serves economic development. It must proceed ahead of the build-up of production. Farm machine research must be based on the needs for overall development of agricultural mechanization. While continuing to carry out product research, renewal, replacement, and filling in associated equipment gaps, it is necessary to strengthen research for agricultural mechanization, conduct scientific forecasting for development of agricultural mechanization, strengthen research on basic design and manufacturing techniques for farm machine products, develop farm machine science and technology that fits in which China's technical and economic levels, and make all-around arrangements for farm machine development tasks on this basis.

(1) Development of Agricultural Mechanization Science and Technology and Research on Technology and Economics. During the past several years all-around zoning of agricultural mechanization has been launched through centralized arrangements made by the state. From a foundation of old agricultural mechanization zoning work, new achievements in agricultural zoning work have been used, emphasis being layed on improving analysis of data derived from the summarization of experiences in agricultural mechanization and on study of technological and economic problems, on investigation and analysis of conditions and characteristics of agricultural mechanization, with designation on the basis of conditions and characteristics and on the basis of the principle of relative consistency throughout the farm machinery system of nine category 1 zones and 36 category 2 zones, the emphasis, steps, and methods for development of mechanization being put forward for the two zone categories. Additionally, on the basis of analysis of adaptability of farm implements and experiments with them plus study of equitable allocation of groups of machines, requirements for farm machinery systems, for development of implements, and for placing them on the market were put forward. This was a task of strategic importance in the development of agricultural mechanization.

Agricultural mechanization must be technically feasible and economically effective. Study of the technology and economics of agricultural mechanization is a foundation for development of so-called applied technology suited to the country's manufacturing and utilization levels, to the level of its agricultural economy, and for the effective development of agricultural mechanization and agricultural machine science and technology. In recent years farm machine scientists, technicians, and management personnel have worked together with economic experts to study technological and economic theories pertaining to agricultural mechanization, and to study technological and economic indicators and evaluation methods, achieving initial results therefrom. They are now actively studying mechanization and the employment of workforces, and mechanization and increases in output and earnings. An additional large number of technological and economic problems such as economic evaluation of new products, new techniques, and new technologies, standards for scrapping old machines, economic analysis of various technical plans, optimum distribution of fuel oil, etc., are in urgent need of research.

(2) Continued Development of New Lines of Farm Implements. Renewal of farm implements cannot be a simple matter of exchanging the new for the old, but rather new articles of higher technological and economic levels must replace outmoded products. Thus, old products must be improved on the basis of requirements for improving efficiency, improving quality, lowering energy consumption, providing a complete line of equipment, san hua [0005 0553], and safe operation. In order to meet the current scale of agricultural production and purchasing power, emphasis must be placed on various kinds of small power machines and associated equipment for plowing, drainage and irrigation, harvesting, processing, hauling, processing of livestock feed, the feeding of poultry and livestock, and farm implements operated by manpower or animal

power. In order to meet needs for improving intensive farming and increasing both yields and earnings, it is necessary to develop a swivel-plow, precision and semi-precision planting machines, machines for deep application of fertilizer, machines for use in the method of slight cultivation that conserve energy and protect the soil, and large cereal grain combines; machines for planting, caring for, harvesting, and processing economic crops, machines for high spraying of pesticides, and machines for processing of agricultural products, dryers, and hauling; machines used for digging ditches, draining water, and clearing away sediment for use in the capital construction of farmland; machines used in the growing, harvesting, storage and harvesting of seeds of pasture grasses to improve pasturelands; 120-160 horsepower tractors and associated farm implements; machines used in the breeding of aquatic products for pond construction, collection and processing of feed, pond harvesting, and in breeding and harvesting in ocean shallows.

(3) Increased Reliability and Useful Life of Farm Machinery. In addition to fulfilling technical performance requirements, modern farm machine products must also be sensibly designed, be reliable, and durable. Therefore, overall improvements are needed in design and manufacture. Study of complete machines must be set on the basis of systems requirements, overall machine unit requirements, and sanhua [0005 0553] requirements. There must be study of the parameters of work components and transmission systems to improve work performance. Modern design methods should be used in combination with traditional experiences in designing. On the basis of strength of individual components, improvements can be effected in the structure and in the selection of materials. It is now possible to gradually set up design and testing standards for farm machine strength beginning with the chassis. In accordance with specialized production requirements, it is necessary to study manufacturing technology and assembly, to improve production management and quality control to assure manufacturing precision and product quality. Testing of models and simulation experiments are necessary to hasten the testing process and shorten the check-out period. In addition, it is necessary gradually to apply the theories and methods of human engineering to study improvements in safety and comfort. Improvement in farm machinery work efficiency, reliability, durability, and comfort can increase both expenditures and raise product costs. Thus it is necessary to study and apply the methods of product economics and value engineering to carry out study and analysis in the expectation of getting optimum economic benefits from the development of farm machinery science and technology.

(4) Extensive Development of Energy Conservation Technologies and New Sources of Energy for Farm Use. In the short term, lack of fuels and electric power are the major limiting factors in development of agricultural mechanization. Conservation of energy consumption and development for use of new energy sources possess extraordinary significance.

One important aspect is improvements in the design of internal combustion engines, which is already being given serious attention and is being actively studied. However, improvements in the operating efficiency of farm implements can also effect very great savings of energy in some cases and are deserving of attention. For example, research on water-powered models of water pumps shows an increased efficiency of more than five percent for underwater electric pumps used in agriculture, and a two to three percent efficiency increase for large axial flow pumps, both of which are scientific research achievements from which results can be obtained through the organization of promotion. Strengthening of management of oil supplies and reduction of leaks and waste of oil supplies, promotion of light plowing methods, multiple operations, and rationally configured implements, and increased efficiency in use can save on oil consumption and should be done.

China's rural villages are farflung, and in many places local energy resources may be developed for use. In the mountain regions of the south, for example, water power resources are abundant. On the grasslands and along the southeastern seacoast, windpower resources exist that can be used. On the high plateaus and in most rural villages solar energy resources are abundant, and in places where there are coal resources nearby, coal and plant stalks may be used for energy. Places that raise a substantial number of hogs may build large and medium size methane pits and use methane to power internal combustion engines.... Local energy must be developed through the adaptation of general methods to local situations to serve agriculture. Promotion for use of small hydroelectric power generators, solar-powered hot water devices, motors that run on either methane or diesel oil, increasing the number of scientists and technicians doing research on energy use, increased use in agriculture of wind-powered machines, and methane gas generating equipment that uses agricultural materials are all necessary.

(5) Establishment of Scientific Research Methods. During the past several years special research units subordinate to government ministries, some provincial and municipal agricultural institutes, and several major farm machinery institutes have strengthened scientific research methods, installing advanced testing apparatus and small or mini computers. Some have set up various specialized experimental facilities such as soil troughs [0960 2864], threshing test benches, water pump test benches, and remote sensing equipment. Some have installed data handling equipment such as spectrum analysis instruments. Certain individual specialities are already able to conduct fairly sophisticated experimental research. However, in the farm machine industry as a whole research methods are still farily backward; specialized testing equipment is fairly little, and simulation experiments or experiments using models and such rapid experimental methods are virtually not used. Because of the lack of fairly large computers, operations requiring a large volume of calculation are impaired. It is now necessary to continue on the basis of development needs to plan to build new experimental equipment. Existing experimental methods should serve scientific research, play a role, and be further improved. In the case of expensive and rare equipment, in particular, there must be mutual sharing among the haves and the have nots and mutual support to increase the equipment's utilization rate.

3

In order to meet the new situation of all-around development of agricultural mechanization, it is necessary to make further use of the role of the available scientific research corps. China has already begun to set up a farm machinery research system composed of special research organizations under government ministries devoted to agricultural machines, tractors, internal combustion engines, livestock industry machines, and the mechanization of agriculture, provincial, municipal, and autonomous region farm machine (and farm mechanization) research institutes and farm machine experimental stations, as well as prefecture and county farm implement offices, promotion stations, industrial plant research and design institutes (departments or offices). Units number more than 1,000 and research personnel number almost 10,000. For a long time, they have been engaged in the design of new products by the institutes. In quite a few units, personnel have concentrated on designing a small number of grain crop planting machines and have made definite accomplishments. However, because of unclear divisions of labor and overlapping work, waste has been considerable. Now, if there is to be all-around development of farm machinery and the science and technology concerned with it, the old rigamarole will have to go and the mentality emancipated to open new territory in farm machinery research, and to blaze a new trail in the development of agricultural machinery.

(1) Development of New Farm Machines By Industrial Plants for the Most Part. Farm machinery plants should serve their customers by rapidly changing products and manufacturing techniques that have endured without change for several decades. They should proceed from real requirements in agricultural production to develop new products. To this end, they must reorganize research, design, and technological ranks within the plants, make use of scientific and technical personnel, and study new techniques for developing new products and for manufacturing.

As the scientific and technical corps in industrial plants grows, research units should gradually cut back on product design functions to devote themselves more to scientific research to advance in depth and in breadth in agricultural machinery science and technology, intensifying research on agricultural mechanization problems, on farm machinery design, manufacturing and basic techniques, and on energy technology for agricultural use. They should strive to develop new techniques and provide new results for agricultural mechanization and for development of new lines of farm machines and their production techniques.

Farm machine research works bears both on industrial technology and on agricultural techniques. Only when industry and agriculture are coordinated can there be results. Currently in some of China's farm machine research a split exists between industry and agriculture, with industry frequently caring nothing for agriculture and agriculture ignoring industry. In proceeding from what helps provide farm machinery research results, farm machine research units should not separate industry from agriculture; farm machine product research and farm mechanization research should be closely linked. Moreover, in order to maintain steady development of farm machine research work, research units should be less subject to the administrative system and should have a certain independence.

(2) Adaptation of Measures to Suit Personnel to Make Use of the Role of Research Personnel. Research work is somewhat exploratory in nature. To a fairly large extent, research results depend on the enthusiasm and creativity of research personnel.

At the present time, China's farm machine research personnel are composed largely of three groups. The first group is old research personnel who have a good theoretical foundation and abundant experience, but who are fairly advanced in years. A large number of them have been engaged for a long time in management of science teaching and are now engaged largely in the work of organizing and leading technical vocational work. The second group is composed of middle age research personnel with a good professional grounding, practical experience, and who are in their prime. They are the main force presently directly responsible for research work, and a considerable number of them are technical mainstay cadres. However, their learning and living conditions are rather poor, and a fairly large part of their time is spent doing housekeeping chores. The third group consists of young research personnel who have been graduated during the past few years. They are young and full of vigor, but their grounding is rather poor as a result of the 10 years of turmoil. Some of them have worked hard and studied arduously for a long time, and are now beginning to become research mainstay cadres.

Now is the time to make distinctions in individual situations and adapt measures to suit personnel in order to make use of individual strengths. To make use of the role of mainstay research cadres, mainstay cadres should form a nucleus with reasonable numbers of associates and assistants being provided in order that their research will bring achievements. Except for a small number of mainstay research cadres required to participate in leadership and management classes, most should be given priority for fairly good working and living conditions, exempted from duties, and allowed to concentrate their energies directly on scientific research to produce research results and gradually become genuine experts, not just specialized experts in name only.

It should be noted that among research personnel today a problem of outdated knowledge exists that requires rotational training and augmentation of required basic theories to meet work needs, mastery of necessary modern research techniques and methods, more active participation in academic exchange, enlivening of academic ideas, and all-around improvement in the quality of researchers.

Research personnel should be good at innovating. They should be able, on the basis of production needs or the needs of scientific and technical development, to create new specialized fields and develop new technologies. Right now China's farm machine researchers are faced with a new situation of all-around development of farm machines. They must boldly accept this new task, pioneer new territory, and make new contributions.

(3) Strengthening of Research Management. The level and speed at which science and technology develop are determined, to a certain extent, by the level and quality of management work. Modern science and technology, and

particularly development of farm product technology, relates to many specialities. For example, research and development of any farm machine product involves agronomy, agricultural mechanization, products and spare parts and their basic technologies, and technical economics. Consequently intensification of research management and the organization of numerous units for concerted action plays an ever greater role in winning research results.

Scientific management should include three main aspects: direction, implementation, and application of results.

First is the direction of research. Farm machine and farm mechanization research is developmental research, and research topics should have fairly well defined goals, i.e., the technical levels and economic results to be attained. Second is organization for implementation, including tasks and forces, balanced conditions, and logistical services to create conditions that will assure orderly development of work on the front line of research. Third is prompt evaluation and spread to production of research results to translate science and technology directly into productivity.

Research management should set up priorities in accordance with research work laws from the selection of research topics, to deciding research topics, to execution, to evaluation, and promotion, and should put forward requirements for individual stages of research.

In order to assure smooth progress in the research work and win anticipated results, it is necessary to establish various kinds of technical, economic and even political responsibility systems. Personnel engaged on problems should mainly be technically responsible and results obtained should be technically feasible. Personnel responsible for tasks and institute (or laboratory) leaders, should be both technically and economically responsible to assure that results have economic value and that economic benefits derive from research investment. Through research they should come up with mathematical models to check on economic responsibility of all categories of personnel. Ours is a socialist country in which all work is under the leadership of a unit CCP Committee. Consequently, CCP committees have comprehensive political responsibility for insuring that units play a role in national construction.

4

To summarize the foregoing, China's rural villages rely on policies and on science to begin to direct agricultural development in accordance with economic laws and natural laws. The state of the agricultural economy is very good and places new requirements on agricultural mechanization for all-around development, for developing farming, forestry, livestock raising, sideline occupations, fisheries, and commune and brigade industries, and for improving the peasants' livelihood.

Farm machine research has to come before development of the agricultural economy. Farm mechanization zoning and research on machine systems and on technological and economic problems must be intensified to provide data for agricultural mechanization and for development of new farm machine products. On the basis of the all-around development of a new situation in agriculture, all-around development of farm machines requires fullness of varieties and numerous specifications. In the short term, emphasis should go toward the adaptation of general methods to specific situations to develop small farm implements and to develop energy saving techniques and new energy sources for agricultural use.

For all around development of farm machines, farm machine research will have to blaze new trails, and bring into play the role of industrial plants in developing new products and new production techniques. Research units should do more scientific research, suit measures to personnel, train and make use of specialists, scientists and technicians, replenish and improve research methods, practice scientific management in accordance with the laws of farm machine research work, emphasize attention to a balance between the direction of research problems and conditions and to the spread of results. In this connection, they should establish research priorities and formulate various kinds of responsibility systems for research and management personnel so that research units will be able to work under fairly stable conditions to produce more results and people of ability.

NATIONAL SOIL CLASSIFICATION SYSTEM EXPLAINED

Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 2, 1982, pp 97-104

[Article by Xi Chengfan [1598 2110 5672] and Zhang Junmin [1728 0193 3046], Institute of Soil Science, Chinese Academy of Sciences, Nanjing: "The Soil Regions of China"]

[Text] Modernization of China's agriculture entails not only steady increases in grain output but also increase in quantity and quality of the agricultural products derived from forestry, animal husbandry, sideline occupations, and the fishing industry to provide the needs of production and of the people's material life. Therefore, rational utilization of water, soil, sunlight heat, and such non-biological resources, and of animal and plant biological resources, and making the most of the advantages that China's natural conditions provide are important tasks in advancing the modernization of agriculture.

Soil is one of the major elements constituting natural resources. Across the 9.6 million square kilometers of China's land are distributed diverse kinds of soils, which form the foundation for overall agricultural production. Because soil properties differ, their production potential and the ways of improving them for use also differ. In order to suit planting to soil characteristics, improve use according to soil characteristics, and conduct management of farming in accordance with soil characteristics, regional characteristics must be analyzed, and soil combinations found in different regions explored to provide a scientific foundation for planning and developing production.

China has conducted soil investigation and research work for half a century. From a foundation of on-the-ground investigation and research of the country's soil and summarization of experiences in the management of soil use and nurturing its fertility, a large amount of scientific data has been accumulated and forms the principal data for conducting soil zoning.

In 1958, Mao Rongzhi [7456 3310 0037] et al proposed the following zoning scale: zone, region, belt, sub-belt, province, soil region, and soil belt. Five zones were delineated, namely the cool temperate zone, the temperate zone, the warm temperate zone, the sub-tropical zone, and the tropical zone, plus the Qinghai-Tibet Plain region. Division of zones into regions was done, in the case of the warm temperate zone, as the forest brown earth region, and the arid forest and forest grasslands cinnamon soil region. The principal basis for divisions were: natural vegetation cover types and soil regionality. Soil regions were subdivided into soil zones and sub-zones, delineation of which was done on the basis of the soil's bioclimatic zone characteristics. Further subdivision was done as flatlands, semi-mountain and mountain regions, and province categories. Division below the province was by soil region. No further division was made beyond soil zone. Soil zoning in the "Collection of China Nature Maps" of 1965 was generally the same as this. It contained six to seven categories. In such a method of delineation the levels of each category are clearly demarcated and the reasoning is rigorous, but because of the overly large numbers of categories and the overcomplexity, soil region characteristics do not stand out clearly enough, and the system is hard to remember and apply.

In 1977, in order to compile the chapter titled "Soil Geography" in the book, "China's Natural Geography " China's soils were delineated and simplified into three categories, namely great soil zone, soil zone, and soil region. First the entire country was divided into eight great soil zones as follows:

1. South China and south Yunnan latosol, lateritic red earth, and paddy soil zone.

2. Chang Jiang mid and lower reaches yellow brown soil and paddy soil zone.

3. Jiangnan and southwest red earth, yellow earth, and paddy soil zone.

4. Huang He mid and lower reaches brown earth, cinnamon soil, and dark loessal soil zone.

5. Northeast black soil, planosol, and dark brown soil zone.

6. Nei Monggol Plateau chestnut soil, and brown desert soil region.

7. Gansu, Xinjiang arid desert soil and oasis soil zone.

8. Qinghai-Tibet Plateau alpine soil zone.

For the second high level category, or soil zone, the principal basis is major differences in soil improvement and use. For the third category or soil region, the major basis for distinction is soil composition.

"Outline of China's Multiple Natural Zones" written in 1980 used a three category system to divide up the country's soil regions.* First of all, in the first category, the entire country was divided into three major natural regions, namely the eastern monsoon region, the northwestern arid region and the Qinghai-Tibetian Plateau region. In the second category, temperature belts were emphasized. From a foundation of summarization of experiences in the growing of tropical plants, China's tropics was divided into poriferal tropics, mid-tropics, and equatorial tropics. The sub-tropics were also delineated into the south, medium, and north sub-tropics. The temperate zone was divided into warm, medium, and cool temperate zones. Thus, the eastern monsoon region was divided from south to north into a total of nine temerature zones on the basis of latitude. Division by corresponding temperature zones was done for the other regions as well. The third region was called an "area" and divided up on the basis of multiple differences of a combination of topography, soil composition, and moisture conditions, every effort being made to describe rather clearly the characteristics of the "area."

---

* Xi Chengfan, Qiu Baojian [8002 1405 0494], Zhang Junmin, and Liu Donglai [0491 2639 0171], 1980: Outline of China's Multiple Natural Zones (Preliminary Draft). Written by the National Agricultural Commission Natural Resources Survey and Agricultural Zoning Commission.

1. Delineation of Soil Zones

There are regular patterns to differentiation and distribution of soils on the land surface of the globe. Individual soil units do not exist independently and in isolation, but are mutually related and structurally form arrangements and make-up of every form and hue, some of them forming soil associations, and some of them forming soil complexes, etc. Under similar conditions, these arrangements and make-ups may repeatedly appear. The co-existence of numerous kinds of soil within a natural unit constitutes the individual characteristics of this region's soil utilization, improvement, and management. When actions taken accord with objective laws, production can go full speed ahead and the ecological balance can be advanced. Conversely, countless conflicts will occur in production, and examples of the lessons of painful experience are too numerous to mention one by one. Consequently, soil zones commensurate with the arrangement and make-up of different soil types have been delineated. In different soil zones, the landscape, vegetation cover, and hydrology must inevitably differ. Identical or similar soil combinations are placed within a soil region, and soil combinations that are strikingly different are delineated as being in a different category of soil region. This helps make the most of the production potential of various different kinds of soil, and helps in the planning and development of production.

Looking at the country as a whole, just what soil characteristics should be included the better to accord with the country's actual soil conditions?

Formerly when soil zoning was done in China, the emphasis was on the soil's bioclimatic characteristics. Such was the case in the zoning of 1958 with the demarcation of five zones (plus demarcation of another single region). The logical rationale for such a method of demarcation is clear, but it contains quite a few conflicts with actual soil conditions in China. Because China's climate has the fine features of rain and heat during the same seasons, but also has temperature zones with which changes in aridity and humidity do not fully coincide, this leads to a series of errors.

In the eastern monsoon region, the temperature zones change with latitude, temperatures declining from south to north, tropics, sub-tropics, warm temperate and temperate zones being from south to north, and stopping at the cool temperate zone latitude. But in China the aridity and humidity situation is one in which the seacoast is humid, and as one moves northwestward, it gradually beomes semi-humid, semi-arid, and extremely arid.

This intermixture of temperature and humidity conditions produces a major impact on the country's soil, vegetation cover, and agriculture and forestry production. North of Chifeng in Hebei Province, for instance, a soil occurs that is both like chestnut soil and also has the characteristics of cinnamon soil, with associated vegetation cover types. As another example, the soils in the southern foothills of the Funiushan and the Nanyang basin are clearly a mixture of southern and northern characteristics. In terms of most recent research data, to say that they possess the characteristics of the relatively dry forest soils of North China mountain regions might be more accurate. Or take southern Xinjiang as an example, where the amount of heat is fine, making it a warm temperate zone where long fiber cotton can be grown, but where there is a shortage of water and where there can be no agriculture without irrigation. Under the aforementioned conditions, it is necessary to consider soil and landscape characteristics together and to conduct concrete analysis in those terms. Therefore, the method of first delineating zones sometimes makes it difficult to outline China's actual soil situations.

Direct use of the method of first demarcating eight great soil zones can resolve some of the aforementioned conflicts. However, yet another situation may arise, namely that this method of dividing regions may place in a subordinate position things that man has yet to bring under control, such as changes in atmospheric temperatures and quantity of heat, thus making difficult a clear explanation of many phenomena. Consequently, in conducting a national soil zoning, a thoroughgoing exploration must be done of the basis for delineating high level categories 2 and 3.

The 1980 mulitple natural zoning that first demarcated three major zones, which were subsequently divided into regions had its desirable qualities. The three major zones outlined the rain and heat occuring in the same season in the eastern monsoon region, and the interplay of seasonal aridity and humidity. In the northwestern arid region, the importance of drought, windblown sand, salinity and alkalinity, and inadequate water in limiting the role of all other natural elements was highlighted. In the southwestern high plateau, the role of high frigidity in limiting productivity was highlighted. Subsequently by demarcating temperature zones for each natural region, the two could be combined to reflect the important differences in China's natural characteristics.

In undertaking national soil zoning, it is necessary, first of all, to make a further painstaking exploration of the problems of divisions within the eastern monsoon region, because eastern China straddles the 50th parallel, is the country's most densely populated area, its most intensively farmed area, and the area in which agricultural production has been going on for the longest period of time. Looked at in terms of soil properties and the agricultural production situation, it may be clearly divided into two parts: The region to the north and south of the Chang Jiang and the farflung area to the south of the Chang Jiang, which belongs to a hot and humid realm of high temperatures and much rain, has soils with varying degrees of calorization, most of which show reactions ranging from mildly acidic to strongly acidic, and which have fairly clear accumulations of free iron and aluminum. Their natural vegetation cover is that of tropical rainforests, monsoon rainforests, and sub-tropical broadleaf evergreen forests. Mostly paddy rice is planted in an annual two crop system of rice and wheat, or in a between two and three crop system. North of the Chang Jiang, the area is largely a semi-humid to semi-arid one where vegetation cover is broad leaf deciduous forests or mixed forests of needle and broad leaf trees, with xerophytic forests, forests, shrubs, and grasses in the west. The soils are predominantly siallitic weathered ones, and many soils have a high limestone content with accumulations of salts being visible in low-lying areas. Crops are predominantly dryland ones, principally corn and wheat, one crop a year or three crops every 2 years being grown. In the far south two crops a year may be seen, thereby reflecting major differences in some soils.

The Qingling Mountains and the Huai He are a major dividing line between natural regions in China, but formerly their soil zoning was largely placed in a subordinate position. Only in this zoning was the eastern monsoon region of the country divided into two major zones to the north and south of this line, the soils to the south of it having a general character of noticeable iron and aluminum content and called the allite soil (or ferro-allite soil) region, and the soils to the north of it comprising the siallitic soil region.

By the siallitic soil region system is meant the features common to the soils from the warm temperate zone to the temperate zone of North China and most of the Northeast. Under semi-humid and semi-arid conditions, most soils are in a siallitic weathered stage with only a weak free iron being visible, and not yet being in the allite stage. This is greatly different from the soils of the south where varying degrees of allite weathered soils have appeared. Under semi-arid conditions, the accumulation of limestone in soils is apparent, with only partial leaching of the limestone, and calcium layer illuviation. Naturally, in a situation of organic accumulation in soils, differences will be very striking. Such changes require further division into another sub-division.

Yet another dividing line for China's soils and landscape are differences inside and outside the Great Wall. The area along the Great Wall in North China may be roughly divided into two major regions. The region south of the Great Wall has cinnamon soil types characteristic of semi-arid forests. The region north of the Great Wall has chestnut soil types characteristic of arid grasslands. North of the Great Wall one crop a year is grown, the crops being mostly cold tolerant and drought tolerant spring wheat, potatoes, and oats. South of the Great Wall three crops every 2 years are grown, consisting mostly of winter wheat, cotton, and miscellaneous grains other than wheat and rice.

Thus, major differences in the soil and natural landscape are reflected in differences in farm and livestock industry production and the crop system. In general, the Great Wall is the dividing line between the siallitic soil region of the eastern monsoon region and the arid soil area of the northwest.

This dividing line extends westward. In the western part of the northeast and parts of the Nei Mongol high plateau, the black earth and chernozem soil beneath the savannah and grassy plateaus of the northeast region appear, which together with the chestnut soil and brown pedocal soil [brown desert soil] formed by the western grassy plateau mark the dividing line between the two great siallitic and arid soil zones. In the traditional form of zoning, this dividing line continued along the southern extension of the Greater Xing'an Mountain Range. However, there is chernozem distributed on both the eastern and western sides of this line. In dividing soil zones, it is best to follow a demarcation line between chernozem and dark chestnut soils, and chestnut and light chestnut soils. This demarcation line is generally identical with the 250 mm per year rainfall line. Such a demarcation has genuine production significance. In both the quantity of hay they produce and the number of livestock they can maintain, the dark chestnuts soil of the west are noticeably higher; without irrigation facilities it is still possible to engage in dryland farming here though the seasonality of drought is pronounced. However, to the west of this line the chestnut soil and brown pedocal soil regions are part of the arid grassy plateau, which are notably lower in their output of hay and the number of livestock they can support. Moreover, only under warping conditions can grain production be undertaken. This is the reason why there are numerous irrigated areas in the river valleys of the western plateau. Yinchuan and Houtao in the Huang He diversion irrigated area, irrigation through diversion of water through small ditches in the foothills of the Daqing Mountains, and irrigation zones made by diversion of melted snow from the high mountains all belong to these irrigated areas. Consequently, on the basis of the aforestated soil characteristics and the natural landscape features, the northwest arid soil region and the eastern siallitic soil have been divided into two major soil regions.

As far as the question of why high mountain soils should be divided is concerned, we felt that delineation of the first category should be done on the basis of differences in major soil characteristics. The Qinghai-Tibet Plateau is a large, high plateau at a low latitude and a high elevation above sea level within China. Its soils and its landscape features are greatly different from those of surrounding regions at lower altitudes above sea level.

Since the late Tertiary Period and throughout the Quaternary Period, the surface of the high plateau has steadily risen, and this has produced extremely great effects on natural conditions on the plateau and on its neighboring areas, making it a unique natural region in China, the soils and other natural conditions of which are very different than those of regions at lower latitudes and lower elevations above sea level.

Since the surface of the plateau is mostly around 4,000 meters above sea level or higher, the mountain systems on it are at even higher elevations. At different elevations above sea level (3,700 meters, 4,300 meters, and 5,200 meters) on the high plateau, soil and farming and livestock raising conditions have rather distinctive characteristics. The usual alpine conceptions do not entirely apply. This is because most isolated mountain peaks at such high elevations are on the ice and snow line, while on the Qinghai-Tibet Plateau, alpine grasslands, semi-alpine grasslands, and grasslands exist. Upper limits for the growing of crops may be above 4,300 meters. On the top of the plateau or in ravines fairly high above sea level grow highland barley, wheat or even fruit trees, and vegetables. These distinctive characteristics are closely interrelated to soil properties.

As a result of the uplifting of the Qinghai-Tibet Plateau and the effects associatied with it, new structural movement is extremely developed resulting in the formation of many large and high mountain systems related to the Qinghai-Tibet high plateau, which cause China to be characterized by many mountains. The area of mountains and hills is more than 65 percent of the total.

In the high mountain systems, vertical differentiation of soils and vegetation cover are apparent. Below the snow line are found cold desert soil, alpine meadow soil and semi-alpine meadow soil. The surface of the high plateau is broad and under overall high and cold conditions, and as a result of differences in aridity and humidity, differences occur in the horizontal plane of the high plateau. Differences in soil patterns resulting from the combination of vertical and horizontal differences produce special soil combinations.

This is the reason for including the alpine soils distributed on the Qinghai-Tibet high plateau as a part of the first great soil category. However, futher analysis is still required for specific delineation. For example, the red earth and yellow earth distributed at a low elevation above sea level on the south side of the Qinghai-Tibet Plateau, and the soil verticle spectrum on it, differ fairly greatly from the soils on the surface of the high plateau. For this reason, in zoning soil, they are classed in a great soil zone with the red earth of the Yunnan high plateau. The elevation above sea level of the Tsaidam Basin in the northwestern part of the high plateau is also very high; however, properties of its soils are akin to those of the northwestern arid soil area, so they are classed in the northwest arid soil zone. Thus after separating out the red and yellow earths at low elevations in the south and the Tsaidam Basin in the north, it is the high and cold features of Qinghai-Tibet high plateau soil that are noticeable. These soils are characterized as having a high underlayment and fierce sunshine, and though their elevation above sea level is high, farming and livestock raising can still be carried out at low latitudes and below high elevations. Therefore, among first category soil regions, neither the system of division into eight major regions nor the system of demarcation by zone was used, but rather three high level categories were divided into four great soil regions as follows:

(1) Allitic Great Soil Region (or Ferro-allitic Great Soil Region).

(2) Siallitic Great Soil Region

(3) Arid Great Soil Region

(4) Alpine Great Soil Region

2. Delineation of Soil Zones

China is situated in the eastern part of the Eurasian continent, and extends from the Zengmu reef in the Nansha Archipelago [Spratly Islands] in the south to the Mo He in Heilongjiang Province in the north covering an area of more than 50 degrees of latitude.

In the course of evolution over a long period of time, diverse soils and natural landscapes have been formed that are suited to the growing of many kinds of plants and crops. Because of differences in moisture conditions and rises and falls in the topography of the temperate zone, the soils that have been formed differ widely. Therefore, delineation of soil zones should occupy a proper position in soil zoning.

The foregoing discussed the overemphasis on soil zonality, or what has been called bioclimatic zonality in former soil zoning, with may phenomena that could not be readily included. Nevertheless, one cannot completely ignore the delineation of soil zones on this account. Consequently, soil zones are a part of the secondary category zones. The basis for their delineation is principally the compatability of temperature zones with soil and vegetation cover. Other influences on soil characteristics and combinations of factors are distinguished in corresponding scales.

Differences in soil properties corresponding to temperature zones exhibit laws of change that generally parallel latitude in the eastern monsoon region, moving from south to north. In the northwestern arid soil region, changes occur somewhat on a slant, largely showing a differentiation from the southeast to the northwest. Soil evolution on the Qinghai-Tibet Plateau is also similar to that of the northwest arid region, aridity gradually increasing from the southest to the northwest. Therefore, in the demarcation of China's soils, three alignments appear.

The eastern monsoon region was formerly divided into tropical, semi-tropical, warm temperate, temperate, and cold temperate zones. Most recently, acting on the basis of a summarization of the growing of rubber and other tropical ecomonic forest woods in China's southern semi-tropics and tropics, taken together with actual differentiations in temperature zones, the tropics has been divided into poriferal tropics, medium tropics, and equatorial tropics zones. Their distinctions are that in the southern semi-tropical zone, only under partial microclimatic conditions is it possible to grow rubber. In the zone ferro-allite soils of the poriferal tropic zone in the northern part of Hainan Island and on the Leizhou Peninsula, rubber can be grown; it is, however, subject to cold damage, and its speed of growth is not as good as in southern Hainan Island. Therefore, in zoning soils, the latosol soil of the former tropic zone has to be divided into fringe tropic zone latosol, medium tropic zone latosol, and equatorial zone soil. The latter is principally the phospho-calcic soil of the various islands of the South China Sea. These have been temporarily lumped into the latosol soil zone for lack of complete data. Each soil zone includes various individual soil belts.

(1) Allitic Great Soil Region. Divided into three soil belts from south to north.

1. Latosol Soil Zone. Includes the area south of the Nan Range, coastal Fujian, and most of northern and central Taiwan Province. Distributed largely as paddy soil, two to three crops may be grown. Longans and lichees are produced on it, as well as bananas in many places.

2. Red earth and yellow earth zone. This is the widest zone of medium and semi-tropical soil in the country including the area of low mountains and hills between Jiangnan and the Nan Range as well as the Sichuan Basin and the Guizhou Plateau. The northern part of the Yunnan Plain is also a part of it. It is a prolific producer of paddy rice and bamboo. One to two crops of paddy rice may be produced annually. Many places also produce citrus fruits, tea, and tea oil.

3. Yellow-brown earth zone. Mostly along the mid and lower reaches of the Chang Jiang and in the Han Shui basin. It is a weakly weathered allitic soil. It grows mostly paddy rice and wheat in a two crop system. In some places, where microclimatic conditions permit, citrus and tea may be grown.

(2) Siallitic Great Soil Region. Divided into three zones from south to north.

1. Brown earth, cinnamon soil and dark loessal soil zone. This is an eastern warm temperate zone soil that is also fairly widespread in China. It includes most of North China and the loess highlands, a semi-moist to semi-arid area. Prolific producer of cotton, wheat, barley and naked barley, and miscellaneous grains other than wheat and rice, two crops per year or three crops every 2 years being possible. It is a major producing area for juicy fruits and dry fruits [e.g. nuts]. In the western part of the loess highlands, soil erosion is fairly serious, limiting development of agricultural production.

2. Dark brown earth, phaiozem, and chernozem zone. These are the principal soils of the eastern part of China's temperate zone. Under semi-moist or semi-arid conditions, the four seasons are distinct. Winters are exceedingly cold, but summers are warm enough to satisfy growth of crops that like coolness. A single crop a year can be grown, and crops include spring wheat potatoes, and sugarbeets, which grow well. Corn and paddy rice may also be grown, but they are prone to cold damage.

3. Podzolic soil zone. Found in a narrow area of China, only at the northern end of the Greater Xing'an Range. Mostly mixed growth of needle and broad leaf forest trees such as larch, white birch, and Pinus sylvestris.

(3) Arid great soil region. Divided into three zones.

1. The kastanozem, brown pedocal, and sierozem zone. An extension of the aforementioned dark brown earth, phaiozem, and chernozem zone of northeastern China, which becomes the kastanozem of the grasslands and the brown pedocal zone of the semi-desert grasslands where short artemesic plants grow, and which is interconnected with the sierozem soil of the semi-desert grasslands at the southern end. The livestock raising industry predominates in these arid grasslands, largely cattle and sheep in the east and goats and camels in the west.

2. Gray-brown desert soil zone. Dovetails with the brown pedocal in the east and extends into the mid-temperate zone desert region with much aeolian arenosol. In the east lies the Tenggeli Desert, and in the west lies the Badanjilin Desert. In the Dzungarian Basin is the Guerbantonggute Desert. There are many irrigated areas below the Tian Shan and the Aerqin Shan.

3. Brown desert soil zone. This centers around the southern part of Xinjiang Province, which is the drought center of the Eurasian continent. From the Hexi Corridor in Gansu westward, it becomes increasingly arid until the center of the Tarim Basin in which lies the vast Takla Makan Desert. Annual rainfall is only 20 to 50 millimeters. As a result of irrigation and many oases made possible by melted snow from the Tian Shan and the Kunlun Shan, long fiber cotton and winter wheat is grown here.

(4) Alpine Great Soil Region. This means mostly the soil on the Qinghai-Tibet Plateau at an altitude above 4,000 meters. Since the plain extends rather widely, it has been divided into five soil zones.

1. Sub-alpine meadow soil zone. Located in the relatively moist southeastern part of Tibet where conditions are fairly good, making it a farming and livestock raising area.

2. Sub-alpine steppe soil zone. Distributed mostly on the north side of the Yarlong Zangbo Valley, which is the main farming and livestock raising region of the Tibetan Plateau.

3. Alpine meadow soil zone. Located mostly around the headwaters of the Yalong, Jinsha, and Lancang rivers, where the terrain is uplifted and the livestock industry predominates.

4. Alpine steppe soil zone. Located mostly on the northern part of the Tibetan Plateau where the terrain is uplifted and where there are many salt lakes. Some livestock raising.

5. Alpine desert soil zone. Connected in the north to the Tsaidam Basin and in the west to the southern Xinjiang Desert. Part of alpine desert steppe.

III. Delineation of Soil Zones

Soil zones are an important element of national soil zoning. They reflect the homogenity of soil make-up and related conditions within zones as well as the generalness of their use and improvement characteristics.

However, such homogenity or similarity of soil combinations applies to broad areas. When zoning soils in provinces or counties, it is still necessary to continue to make fine distinctions. Take the Huang-Huai Plain as an example. This is a self-contained soil zone unit within the brown earth and cinnamon soil zone. But within the zone, differentiations of soils are still very obvious. Cinnamon soil is found only in alluvial fans at the foot of mountains and in places on the plain where the ground water table is fairly deep. The broad plain may continue to be divided into the North China Plain north of the Huang He, and the Huangfan Plain to the south of the Huang He where fluvo-aquic and saline-alkaline soils predominate. At the southernmost end of the Huang-Huai Plain, sajong black soils predominate.

Take the North China Plain as another example. It may be finely divided into piedmont alluvial fan fluvo-aquic brown soil, alluvial plain fluvo-aquic soil, saline-alkaline soil, and saline coastal soil. These subdivisions below soil region are of reference value for soil improvement and use.

In undertaking a zoning of national soil regions, the basic characteristics of broad soil regions must be delineated to make individual units in soil regions distinct. Soil combinations with identical or similar characteristics should be grouped together, and those with obviously different characteristics should be separated out. Illustrative examples are given as follows:

Example 1. Traditionally when discussing the loess highlands, the region of Shanxi, Shaanxi, and Gansu to the west of the Taihang Mountains is collectively called the loess highlands. Thus, because the extent of the loess highlands is overly large, when discussing soil improvement and water and soil conservation in the loess highlands, endless debate results from the object of discussion not being the same. One must know that the Yan Shan rise in the north, and that the Taihang and Luliang mountain system than extends to the south is a mountain area of soil and rock. Though there are also loess accumulations in the ravines and valleys of rocky mountain lands here, its characteristics differ rather greatly from the loess mesas, ridges and hills to the west of the Luliang Mountains. Therefore, if the loess highlands are delimited in a small sense, only the region where the less soil layer is deep (averaging between 30 and 280 meters), erosion is serious, and which is cut up into rounded hills, loess ridges and loess mesas is meant. This is a region where vegetation cover is sparse, consisting mostly of grasses, and is called the loess highland loessal soil and dark loessal soil area. The soil and rocky mountain area to the east, on the other hand, is called the North China mountainland brown soil, skeletal cinnamon soil, mountain brown earth zone, which is the principal area for the growing of fresh and dry fruits such as Chinese chestnuts, walnuts, apricots, and persimmons. Here the valleys and basins are major agricultural areas. But the large river valley plains form yet another soil region.

In the two aforementioned soil regions, soil make-up is different, and distinctions in their use and improvement are also fairly great.

Large river valley plains such as the Fen He and Wei He river valley plains as well as the various forms of land on their banks such as the first, second, and third grade mesas, have been substantially uneroded or only slightly eroded. Agricultural production there is consistent, and it is a farming area with consistently high yields. It differs greatly from the loessland highlands, which have been badly eroded. Thus it requires delineation as a soil area called the Fen and Wei valley fluvo-aquic soil, cumulative cinnamon and cinnamon soil region.

Therefore, the soil region that had formerly been lumped together under the term "loess highlands," has now been defined as the North China mountainland, the loess highlands, and the valleys of the Fen and Wei. In this way soil region concepts are clarified, so that discussion about the direction of improvement and use of different soil regions will have a clear orientation.

Example 2: In the division of soil zones in the Sichuan Basin, should the Sichuan Basin be maintained as an entity when zoning the soil in such a large basin? Or should it be divided up in a suitable way while retaining its general outlines. This merits exploration.

We have divided lowland areas of the Sichuan Basin into the Chengdu Plain paddy soil region and the Sichuan Basin purplish soil and paddy soil regions. As to just how to distinguish the mountain regions of eastern Sichuan and the mountains surrounding the Sichuan Basin is also a question meriting deep study. The Huayong and Jinyun mountainlands of eastern Sichuan have mostly yellow earth, but their valleys also contain much purplish soil distributed in high hills, which is very much the same as that of the purplish soil hill area of eastern Sichuan, and which should be made a sub-category of that region. However, a comparison of the mountains surrounding Sichuan with the Guizhou Plateau shows their soil properties and landscape characteristics to be virtually identical. Thus, the mountains surrounding Sichuan and the Guizhou Plateau can be grouped together as a single soil region in which yellow earth, rendzina, and paddy soil predominate. Since soil properties of the Kunming Plateau and the Guizhou Plateau distinctly differ, they cannot be lumped together as the Yunnan-Guizhou Plateau, but should be divided into two soil regions.

Example 3. The vast expanse of mountains and hills to the south of the Chang Jiang form a major part of China's semi-tropics. They cover a vast area in which natural conditions are very good, making them major areas for the development of agriculture and forestry. Formerly it was customary to refer to them collectively as the Jiangnan hills, when, in fact, mountainlands account for a substantial area. The make-up of the soil of the rolling hill regions and the folded mountains, as well as their use and improvements differ fairly greatly. Consequently, this vast region has first been broken up into the Jiangnan hill red earth and paddy soil region, which comprises mostly Hunan and Jiangxi, but also extends eastward into the Red Basin in Qu County, Jinhua Prefecture, in Zhejiang Province. In landforms, mother material, and soil make-up, this Red Basin greatly resembles the adjacent region, so it is classed as a single soil region. Additionally identified are the Jiangnan mountainland red earth, yellow earth, and paddy soil regions including the north slope of the Nan Range, the mountainlands of Fujian and Shejiang, and the mountainlands of southern Anhui and northern Jiangxi. The hill soil regions south of the Chang Jiang are at a low elevation above sea level and the slope of the terrain is fairly gentle. They are a major farming area requiring attention to improvement of the red earth. The mountainlands south of the Chang Jiang are at a fairly high elevation, most mountains below 1,000 meters. They are characterized by extremely well developed interspersed large and small mountain basins, each of the basins traversed by streams, with mostly wetlands in the middle of the basins and terraces climbing the sides of streams. The soil is largely red earth. High hills and low mountains are mostly red earth and yellow earth, largely covered with common broad leaf forests. These basins are major producing areas for bamboo, wood, and economic trees such as tea oil, tung oil, and citrus fruit. In ravines and along mountain slopes of varying heights where water is adequate, one finds terraced fields where rice is grown. They serve as fine bases for multiple kinds of farming. Of course, provincial and county level zoning has not been carefully done.

Example 4. In China'a northwestern arid region, mostly various kinds of desert soils are found. The arid region has several large basins including the Tarim and the Dzungarian, plus the Hexi Corridor. These basins and their surrouding mountainlands form a self-contained natural system. Their soils and other features have yet to be carefully delineated. In the center of the basins are vast arid deserts such as the Takla Makan Desert and the salt lakes to the east of it in southern Xinjiang. Mountains surround the basins. Take the Tian Shan, for example. It has brown pedocal soil, chestnut soil, and even black desert soil, which is distributed in a vertical spectrum as the mountains rise. At the forest line, one sees gray cinnamon forest soil. The melting of ice and snow in the high mountains forms the source of irrigation water for oases in the basins. Thus, three distinct soil areas are formed: (1) the Tarim Basin, Lop Nor brown desert soil and aeolian arenosol region, (2) the Tarim Basin fringe irrigated cumulative soil, brown desert soil, and saline soil region; and the (3) Tian Shan gray-brown soil and semi-alpine meadow soil area.

The foregoing examples demonstrate the existence of broad regional soil region concepts in the zoning of soils. Insofar as possible, soils are grouped together in the same soil region on the basis of their similarities in make-up, and thus the soil make-up of one soil region and another is clearly differentiated making for easy identification. All graduations of fairly small distinctions have been identified in the scale for different regions provided below. In national terms, soil regions should not be divided up too finely or into too many sub-regions. For example the Altai Shan gray forest soil, semi-alpine meadow soil region is a soil region formed from the combination of several discontinuous soil tracts containing soil with similar properties. The Tarim Basin fringe irrigated cumulative soil, brown desert soil, and saline soil region is a similar situation. In formulating agricultural production plans, measures can be adopted on the basis of differences and similarities between one soil region and another.

ZHOU ZIJIAN VISITS, REASSURES COMMUNE MEMBER

OW041351 Hefei Anhui Provincial Service in Mandarin 1100 GMT 3 Aug 82

[Newsletter by station correspondent (Ye Shihe): "The Governor Makes Us Feel Reassured"]

[Excerpts] Zhou Zijian, acting first secretary of the Anhui Provincial CCP Committee and governor of Anhui, inspected Jingde County in mid-June. After a briefing by county and commune leaders, he paid a visit to (Lu Jinsheng), a commune member of the (Fengxi) No 4 production team of (Niaoshou) commune, despite the rain. He encouraged (Lu Jinsheng) to vigorously develop production and get rich through work as quickly as possible.

(Lu Jinsheng's) family consists of six members, three of whom are able-bodied workers. (Lu Jinsheng) himself is a hardworking and capable man. He has been a production team leader for more than 20 years. He is good at farming and diversified undertakings. In addition to 7.5 mu of land which the family farms under contract, the family also grows ramie and keeps sows and cattle. The family's annual income from farming and sideline production may go as high as 3,500 yuan, averaging 600 yuan per person.

Seeing the fine ramie crop at (Lu Jinsheng's) home, Comrade Zhou Zijian said happily: Your ramie is very good.

(Lu Jinsheng) said what he had wanted to say for a long time: Every family here grows ramie. It is a major sideline production and source of income. However, the commune members are afraid that the policy might change and that they could be stuck with their unsold ramie.

Comrade Zhou Zijang said: The state is going to set up a ramie mill. When that happens, there will not be enough ramie to meet demands.

(Lu Jinsheng) said: That is good. We are reassured.

BRIEFS

TEA PROCUREMENT--By 10 July, Anhui had procured 616,000 dan of tea from tea growers, thus overfulfilling this year's state procurement plan by 4.5 percent. The 1982 procurement is 95,000 dan more than the 1981 procurement. [OW060130 Hefei Anhui Provincial Service in Mandarin 1100 GMT 16 Jul 82 OW]

ANQING PREFECTURE EARLY RICE--Anhui's Anqing Prefecture has reaped a bumper harvest from its 2.53 million mu of early rice fields, with per-mu yield reaching 750 jin and total yield 1.9 billion jin. [OW140351 Hefei Anhui Provincial Service in Mandarin 1100 GMT 13 Aug 82 OW]

GUZHEN COUNTY AGRICULTURAL PRODUCTION--Guzhen County in Anhui has increased its total annual grain output from 237 million jin to 554 million jin in 3 years since the convening of the 3d Plenary Session of the 11th Party Central Committee. The total income derived from agricultural production achieved an annual increase of 22 percent in both 1979 and 1980 and reached 183 million yuan in 1981, more than double that of 1980. The county's total wheat output has reached 285 million jin, 35 percent more than last year. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 12 Aug 82 OW]

ECONOMIC DEVELOPMENT--According to a report submitted by Anhui's vice governor Guo Qiziang on 17 July 1982 to the 14th meeting of the Standing Committee of the Fifth Anhui Provincial People's Congress, the total output of summer grain is expected to reach 10.26 billion jin and that of rapeseed is expected to reach 17.46 million dan in the province. The total industrial output value for the first 6 months of 1982 has reached 6.95 billion yuan in Anhui, fulfilling 49.6 percent of the annual target assigned by the state. By the end of June 1982, 1,397 million jin of summer grain, 400,000 dan of spring tea and 56,000 dan of spring silk cocoons had been procured by the state. [Hefei Anhui Provincial Service in Mandarin 1100 GMT 20 Jul 82 OW]

RICE HARVEST--Despite incessant rains 9-24 July, which brought 300 to 400 mm of water to the rice fields, Anhui Province had, by 6 August, harvested 10 million mu of early rice, or 90 percent of the total to be harvested, while planting 8 million mu of late rice. PLANNED PARENTHOOD STRESSED UNDER RESPONSIBILITY SYSTEMS

Beujing RENKOU YANJIU [POPULATION RESEARCH] in Chinese No 3, 1982 pp 30-32

[Article by Xiao Sanhua [5618 0005 5478] of the Population Institute of the Guangdong Province Academy of Social Sciences: "How Planned Parenthood Work Should be Carried out After Implementation of Production Responsibility Systems in the Rural Areas"]

[Text] After the Third Plenum of the 11th Party Central Committee, rural production systems were transferred to lower levels and a variety of production responsibility systems were implemented in rural areas, breaking new paths for resolving a situation in which rural production had become bogged down. But after the systems were transferred to a lower level, a rise in the natural population increase appeared in rural areas. How can this new problem which has arisen under new circumstances be resolved? This is the subject of this article.

I. Responsibility systems, such as occupational contracts or household production contracts to labor, which link compensation to production, are an important part of the distrubiton by work system. This is particularly evident in improving the lot of poor and backward units.

However, things have a tendency to develop in complex and interrelated ways. After the responsibility system for household contracts was shifted to labor, the phenomenon of no one being in charge of planned parenthood appeared in rural areas; this produced an anarchic attitude regarding childbearing and the birth rate started to rise again. After the system was changed, the work point compensation system below the production brigade level was completely abolished. The past regulation of discounting the labor work points earned by a couple with too many children was hard to enforce. In some places, when responsibility for land was allocated under the system of contracting to the household, it was stipulated that those with too many children should receive less land for which they were responsible, but in places with little population and a lot of land there was no problem about giving less land. In some places where incomes were high, the household concerned didn't even mind the levying of fines for excess children.

Such problems appear to be obstacles which were created after the implementation of the responsibility system, but actually this outlook is a little one-sided.

Marxism holds that population production is in the sphere of social production and is restricted by the methods of social production. The level of a society's economic development based on a certain level of productive forces determines the state and scale of the population growth of the society. At present, China's rural economy still retains animals as motive power; with a level of agricultural production forces consisting largely of hand labor, in which machinery has not yet replaced human labor for cultivation, the peasant family is the production unit and the amount of economic income is determined by the strength of the labor force. In addition, due to the relatively low standard of living, the cost of raising children is low, and since the technical demands of agriculture are not high, expenses for educating children are not great. This extremely low level of agricultural production is reflected in childbearing, which is high. As a result, the production responsibility systems in the rural areas, after it is implemented, cannot be expected to play any determining role in changing the birth rate.

However, the view of childbearing which proceeds from the individual interests of the small rural economic unit can, through socialist propaganda and education, administrative measures, economic rewards and punishment, under the premise of the primacy of state and collective interests, through planned parenthood, be changed so as to control the reckless growth of population. In the past 10 and more years, planned parenthood work has made enormous achievements sufficient to prove the point. Since the seventies, when we began to stress planned parenthood, the natural population growth rate for the entire country dropped from 12.72 per thousand in 1976 to 11.7 per thousand in 1979, which is lower than the 17 per thousand level for natural population growth worldwide for the same period. Rural natural population growth rate for the entire nation dropped from 24.29 per thousand in 1971 to 12 per thousand in 1979. The planned parenthood rate went from 10 percent in 1971 to 70 percent in 1979. The birth rate of 33.59 per thousand for the entire country in 1970 dropped to 17.90 per thousand in 1979, or 56 million fewer births nationwide, which is equal to giving birth to fewer people than the entire population of Guangdong Province. Thus, transferring agricultural production systems to lower levels and doing a good job of rural planned parenthood is entirely possible. The crux of the problem which appeared earlier was that our commune and brigade cadres and masses relaxed planned parenthood work. For a time right after a change in a system on policy we should not be surprised at some ideological problems in society. If only we strengthen study, raise understanding, establish policies well, do a good job of propaganda education among the masses, strengthen the ranks and lead the masses, planned parenthood work can be done well.

II. How should we carry out planned parenthood work in this new situation? Practice in many areas proves that it is necessary first of all to resolve the key problems. The Central Committee said: Rural areas generally should advocate one child, stop at two and not have a third, and this is completely correct. It conforms both to national circumstances and the will of the people, and it should be firmly carried out. Whether from theory or from method, "not having a third child" is much easier than having one child and stopping at two. Today (i.e., 1981) the excess births in many provinces nationwide is 30 percent or more (Yunnan, 30 percent; Hebei, 30 percent;

Guangdong last year 30 percent). The nationwide multiple birth rate is still 20 percent. If we stop multiple births and other things remain the same, the natural population growth rate may drop to below 8 per thousand. In the past some people said: "I'm a citizen of China. Other people have multiple births, why can't I have one more?" Some people were clearly ready to have only one, but because they were influenced by others having more children, they gave up the idea of having only one, so the influence of this thinking was very great. Not having a third child is a matter which planned parenthood work should address first of all, for this is a strategic measure.

Next, it is necessary to clearly stipulate the scope of the"stop at two children" policy so that "not having a third" will not go so far as to produce the misunderstanding of whether or not one can have a second child. In the spirit of the directives of the CCP Central Committee and the State Council, for those rural areas where the masses demand a second child because they are really having problems, after investigation and the implementation of planning arrangements, contracts should be signed with the women of childbearing age. In this way the limitations of the "stop at two children" policy will be specific and clear, and this will establish a firm foundation for stressing "stop at two children" work.

III. Marxism holds that the production of material goods must adapt to the production of mankind itself. Resolving our population problem requires that we stress the two kinds of production together. After the implementation of responsibility systems which link compensation to production, the advanced units in planned parenthood in Pingshi Commune in Lechang County, Nankou Commune in Nei County and Gaoyao County (all in Guangdong) established models of how to improve planned parenthood work. Their method was to make both agricultural production and planned parenthood part of the responsibility system so that the method of "stressing both kinds of production together" was further well grounded. Specifically, the "stress food, money and people together" program should be implemented. When the work group or household giving guarantees signs a "dual guarantee" contract with the production brigade, it guarantees agricultural quotas and planned parenthood quotas together. A person's parenthood quota is set by the work group and carried out by the individual. Cadres, masses and individuals all know who should have a child and who should not have another child, and this plays a supervisory and restrictive role. The work group must certify to the production brigade that it carried out the parenthood norms and that it did not have any excess births outside of the planning.

The "dual guarantee" contract also stipulates the joint checking and fixing of rewards and punishment. If the production and parenthood quotas are both met, then the entire bonus is received: 70 percent for agricultural production and 30 percent for planned parenthood. If the agricultural production mission is completed but planned parenthood is not, then only 70 percent of the bonus is given. At the same time, the production brigade stipulates that if there are excess births outside of the plan, then an excess birth ration will be deducted from the total grain ration of the commune members of the entire group, and this further links planned parenthood to the personal interests of each commune member. The commune and the brigade also adopt the deduction-by-level method with regard to the brigade and the production brigade respectively; one level deducts from the next lower so that the levels are closely linked. This causes people to be concerned about each other and the cadres and masses manage in tandem so that the "dual guarantee" system is well established. The commune, brigade, production brigade and work group (household) all give guarantees to the level above them regarding a double heavy mission. The two quotas are assigned together at the beginning of the year, checked at midyear together and reported together; at the end of the year they are summarized together and evaluated together. This makes planned parenthood work regularized and systematized.

In the past, planned parenthood work was always of a crisis nature: during the high tide activity was furious, but as soon as the high tide passed it cooled off, so the results fell short. Because it implemented the "dual guarantee" and as a result of evident achievements in the "stress food, money and people together" program, Nankou Commune in Mei County was declared an advanced county unit. In 1980 the birth rate was 15.1 per thousand, the natural population growth was 9.2 per thousand, the multiple birth rate was 2.1 percent, and there were 11 brigades which did not have third births, so the population was better controlled. After Pingshi Commune implemented the "dual guarantee" contract system, there were great developments in agriculture, forestry, animal husbandry and sideline production, and superior results in planned parenthood work, too. At the end of last year the natural population growth rate was 3.66 per thousand, the planned birth rate was 84.9 percent, and the late marriage rate reached 96.3 percent. In the first quarter of this year the single-child birth rate increased from last year's 77.4 percent to 94.4 percent, and 10 of the 16 brigades in the entire commune achieved 100 percent in the single-child birth rate. Of the 150 production brigades in the commune, 129 did not have a third birth.

To summarize, after implementing household guarantees or some other responsibility system which links compensation to production in rural areas, the following are the main methods of doing a good job of planned parenthood work:

1. Leadership thinking and understanding should be unified, and party members and cadres should take the lead by setting an example. For example, in Huilong Commune in Gaoyao County, the cadres advocated that each couple have only one child, but they ran into heavy resistance so it was very hard to launch the campaign. After the commune cadres launched a campaign to study relevant population theory, the relationship between population and the four modernizations and the Open Letter from the Central Committee, they raised their understanding, unified their thinking and resolutely took the lead in having only one child, and this played a very good role in planned parenthood work. Because the commune cadres all received single-child certificates, one level spurred on another, the leadership spurred on the masses and very quickly this promoted a high tide of having only one child throughout the commune. There is a saying: "The village looks to the village, the household looks to the household, the commune members look to the cadres and the party members look to the party branch." It is necessary to emphasize that "the cadres should do first what is demanded of the masses; and the cadres

"within the party should do first what is demanded of the cadres." The Central Committee's Open Letter demands that party and league members and cadres take the lead by setting an example.

2. Propaganda and education work should be launched vigorously and a careful job of ideological work should be carried out. China has a several thousand year history of feudal society, and feudal influences on marriage and childbirth are very profound in the rural areas; the feudal ideas that "the more children, the more happiness" and "boys are honored, girls are inferior" are deeply rooted in the rural areas. Advocating having only one child can meet stiff resistance. Having only one child is an ideological revolution in transforming social customs. Gaoyao County's ideological education work adopted the unity of theory and practice; using materials on hand by settling balances helped the masses easily to comprehend the principles and get a real life education with very good results. The cadres guided the masses to calculate three accounts: the disadvantages of the increased burden on the state, the collective and the family of reckless population growth, the advantages of planned population growth; and the economics of a couple having only one child; they showed that keeping the population under 1.2 billion is related to the future of the peoples of the country, the happiness of future generations and the integration of long-range interests and immediate interest, state interests and individual interests. Through account balancing education the county's single-child rate rose from 7.8 percent in 1979 to 47.6 percent last year; 168 units in the county reached a single-child rate of 100 percent.

3. Do a good job regarding policy and implement bonuses and fines. There are seven relevant stipulations in the Guangdong Planned Parenthood Regulations which provide for bonuses for those who have only one child. To the extent possible, brigade and production brigades should make supplementary stipulations which provide for a variety of consideration so that visible immediate benefits will be received. This not only broadens the impace of single births, but also further establishes a solid foundation for the single-child rate. On the other hand, there are economic penalties (work points cannot be deducted, so fines are used) for multiple births or unplanned births to be used for education in implementing the policy of bonsues and fines, and this plays a great role in stopping additional births. For example, Pingshi Commune adopted economic measures, implemented a bonus and fine policy, carried out a mass pledge and implemented measures to increase bonuses and fines to make the policy work. From January to April of this year there were 232 instances of the four procedures (including 60 induced abortions, 35 ligations of men and women and 142 ring emplacements), so that the rate of single births rose from last year's low, 77.4 percent, to 94.9 percent.

4. A staunch and stable planned parenthood work corps should be established. Since responsibility systems linking compensation to production and "dual guarantee" contracts have been implemented, advanced units have turned around the passive situation of the past and have established a specialized corps responsible for day-to-day work. Brigades and production brigades have also alerted women leaders and barefoot doctors that when, in the process of carrying out routine examinations, a pregnancy which is outside of the plan is

discovered, they are to report it immediately and take precautionary measures promptly. Occupational brigades have duties and rights to provide extra allowances. They should keep their minds on their work, have clearcut responsibilities and play an important role.

5. The down-to-earth work of birth control measures should becarried out after a certificate is secured. The age of parents of a single child securing a certificate is usually between 25 and 30. After securing their certificate, to guarantee that they do not have any excess births, long-term measures should be taken. Ordinarily, ideological education should continue along with regular examinations so that there are no excess births.

In summary, the fact that the birth rate began to rise again after the rural production responsibility systems were transferred to lower levels was not due entirely to the responsibility systems, but was caused by the fact that the cadres and masses were not clear in their thinking and became too lax in their work. After many communes and brigades combined responsibility systems, carried out "dual guarantees," and "stressed food, money and people together," obvious results were achieved. In the future, thinking should be unified, policy should be unified, cadres should take the lead, measures should be established, propaganda should be carried out well, and policies should be honored to regularize and systematize planned parenthood work so that population control work can be done well.

USE OF ECONOMIC CONTRACT LAW URGED IN AGRICULTURAL CONTRACTS

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 5, 1982 pp 17-18

[Article by Li Yuanhe [2621 3293 0735]: "Study Economic Contract Law as a Means To Improve the Agricultural Production Contract System"]

[Text] The "Economic Contract Law of the People's Republic of China," passed by the Fourth Session of the Fifth National People's Congress, covers economic contracts signed by legal entities in China, and supplementary articles state: "Economic contracts concluded between individual enterprises and rural commune members and legal entities should be executed with reference to this law." Agricultural production contracts are economic contracts concluded between rural commune members and legal entities (production brigades) and should be honored with reference to the relevant stipulations of the Economic Contract Law. On the basis of the actual practice of the agricultural production contract system in force in Gansu, I would like to discuss some preliminary views and opinions on executing [contracts] with reference to the Economic Contract Law.

On Concluding Contracts

First of all, it is necessary to understand the basic principles which must be observed in concluding a contract and clarify the boundaries between a valid contract an an invalid contract. The Economic Contract Law stipulates that an economic contract concluded between legal entities must: 1) "obey state law and conform to the demands of national policy and planning; and 2) "follow the principles of equality and mutual benefit, negotiated agreement, and equal value compensation." On the other hand, "contracts which violate the laws, policies and planning of the state," "contracts which are concluded by deception or coercion," and "economic contracts which run counter to the national interests or the common interests of society" are invalid economic contracts and are not legally binding. Presently concluded agricultural production contracts must emphasize the following: 1) The unchangeability of the collective ownership of the basic means of production must be upheld. Land and other basic means of production of the contracting group, laborer, or household belong to the production unit, and the contractor is not permitted to buy or sell, rent, mortgage, allow to lie fallow, built on or use this land for graves. 2) The national interests and the common interests of society must be protected. National resources and the collective resources of neighboring communes and brigades may not be used as a unit's resource and contracted to commune members. Damage to state resources or to the collective economic interests of neighboring units through managing contract production is not permitted. 3) There must be conformity with the demands of the national plan. Contracts are to be concluded in accordance with the direct quotas and guideline quotas handed down by the state, integrated with the unit's actual circumstances and implemented concretely by group, laborer and household. 4) The rights, responsibilities and benefits to both sides must be negotiated in order to achieve agreement through thorough discussion by production brigade commune members and the masses.

Next, the important provisions which the agricultural production contract should have should be made clear. Regarding the important provisions which the Economic Contract Law stipulates an economic contract concluded between legal entities should have, the agricultural production contract generally should contain provisions concerning the following: 1) the contract quantity and usage demand for important means of production, such as land, draft animals and machinery and tools; 2) the contract production plan, output and income; 3) the method of distributing commodities and income, and stipulations on bonuses and penalties, time limits and methods for completing the state mission and the collective's retained share; 4) nonfulfillment by either party of its economic responsibility under the contract; 5) discussion by both parties of any other provisions that must be fulfilled.

Third, the various types of contracts and agreements should be conscientiously concluded. The contract must conform to principle, the content must be complete, the stipulations must be specific, the responsibilities must be clear, and every effort must be made to make it easy to carry out. There should be three copies of the contract: the production brigade and the contracting unit should each get one copy and one copy is to be sent to the brigade.

On Honoring the Agreement

The Economic Contract Law stipulates that an economic contract between legal entities "is established according to law, i.e., it has the force of law and the entities involved must either completely honor or terminate the contract." This stipulation completely fits the agricultural production contract. The group, laborer or household which is the contracting unit must use the basic means of production, establish a production plan, perform the production contracted and complete the mission to be handed over to the state and that to be retained by the collective in accordance with the demands of the contract. The production unit which receives the guarantees must supply the basic means of production for the contracted unit in accordance with the requirements of the contract. Both parties must meet all the commitments stipulated in the contract; they cannot avoid the difficult parts and carry out the easy ones, honoring only some of the commitments and ignoring others.

In principle, the Economic Contract Law stipulations on changing and terminating economic contracts are also suited to agricultural production contracts. The present agricultural production contracts permit changes or termination mainly in the following situations: 1) if the contract is difficult to honor in accordance with the original provisions due to severe natural disaster, the contract can be altered and the relevant quotas readjusted; 2) if certain specialized production items of the contract cannot be honored because of severe illness or injury to the contractor, the contract can be altered or terminated; and 3) if the state plan on which the contract is based is revised or cancelled, influencing the honoring of the contract, it can be altered and the relevant quotas readjusted. If some of the provisions of the contract are not altogether reasonable due to lack of experience, generally the contract should be honored as originally concluded, and then readjustment and improved in the next year.

The Economic Contract Law also has clear stipulations with regard to breaking an economic contract. Breaking an agricultural production contract should be handled depending on circumstances in accordance with these stipulations: 1) if a contract cannot be honored in whole or in part due to severe natural disaster, the relevant quotas can be readjusted in accordance with the situation, and all or part of the economic responsibility can be absolved; 2) if a contract cannot be honored in whole or in part because of a mistake made by one or both parties, the party or parties who have made the mistake should accept responsibility for breaking the contract; and 3) if a contract cannot be honored in whole or part because of a mistake made by an upper echelon leadership organ or responsible professional authority, responsibility for breaking the contract should be taken by the upper echelon leadership organ or responsible professional authority.

On Handling Contract Disputes

First of all, the parties involved should try to negotiate a resolution. According to the stipulations of the Economic Contract Law, after a dispute arises in an agricultural production contract, the production brigade should promptly investigate and instruct the party or parties in violation to act in accordance with the provisions of the contract. For contract disputes which are complex and involve a broader area, the production brigade should call a meeting of all commune members and democratically negotiate a resolution. Production brigades acting as legally declared representatives of a legal entity should take the lead in honoring contracts and implement the negotiated decision of the production brigade. Before contract disputes which cannot be resolved through negotiation are mediated and arbitrated by upper echelons, the production brigade should adopt measures to prevent the situation from exacerbating and, to the extent possible, reduce the economic loss to the nation, collective and individual commune members. As long as the work is done well, the majority of contract disputes can be promptly resolved within the production brigade.

Next, do a good job of mediation and arbitration work on contract disputes. Regarding the stipulations of the Economic Contract Law, the brigade and commune should be asked to mediate and arbitrate agricultural production contract disputes which cannot be resolved through negotiation; the other party may directly ask the brigade and commune to mediate and arbitrate disputes involving a brigade cadre who breaks a contract. The brigade and commune should accept the request, promptly organize their forces, investigate, hear the opinions of the masses and both parties to the contract, then mediate and arbitrate. They should carry out the policy of mediation first, arbitration second, persuading the party or parties breaking the contract to honor it, and thus reach a mediated agreement. Where responsibility for breaking the contract is clear but both sides' views of how to deal with it are not the same, the mediation unit will make an arbitration decision. Both mediation and arbitration should seek a fair and reasonable resolution, proceeding from what is best for production and unity, in accordance with the state law, statutes and policies, with the original contract as the basis. The contract signers should implement the mediation or arbitration decision, and the commune and brigade should oversee their compliance.

Third, the small number of contract disputes which still cannot be resolved by mediation or arbitration can be taken to the local people's court by the party involved. Other civil disputes which arise as a result of the contract dispute can also be taken directly to court. The court should hear cases of agricultural production contract disputes and decide them according to the law. The court's decisions are binding and the parties must carry them out.

On Contract Management

Agricultural production contracts should strengthen contract management in line with the demands of the Economic Contract Law concerning economic contract management.

The aim of agricultural production contract management should be to improve the agricultural production contract, reduce contract disputes, strengthen the handling of contract disputes, improve the contract fulfillment rate and the quality of fulfillment, strengthen and improve the agricultural production responsibility system, fully mobilize the initiative of commune members and the masses, raise the level of cadre management and promote the development of agriculture.

Agricultural production contract management organs: responsible agricultural sections should manage voluntarily in accordance with state stipulations. Specific opinions: these should be carried out by county, commune and brigade.

The main function of agricultural production contract management: the grassroots level agricultural production contract management unit should stress the following in accordance with the demands of the state with regard to economic contract management: 1) give guidance to production brigades and the commune member masses in concluding agricultural production contracts; 2) oversee contract implementation; and 3) mediate and arbitrate contract disputes.

With the spread of the agricultural production contract system, it is essential to formulate agricultural production contract management provisions. I propose that the relevant sections organize their forces, select a model county or commune, do some in-depth investigation and study, and in regard to the Economic Contract Law, formulate draft provisions for agricultural production contract management and gradually supplement and improve them in practice.

PROBLEMS OF COTTON FUSARIUM, VERTICILLIUM WILT DISCUSSED

Beijing RENMIN RIBAO in Chinese 7 Mar 82 p 2

[Article by Shi Leiyan [4258 4320 1484] of the Plant Protection Institute of the Chinese Agricultural Sciences Academy: "Fusarium and Verticillium Wilt of Cotton"]

[Text] Fusarium wilt and verticillium wilt of cotton are two important worldwide diseases. These two diseases occur in all of our nation's major cotton-producing regions, and cotton production has suffered from varying degrees of damage. Generally, the affected plants produce 20 to 30 percent less in yield.

Fusarium wilt and verticillium wilt of cotton are diseases that cause withering due to the invasion of the vascular bundles by parasitic fusarium fungi and verticillium fungi, which are low plant fungi. Although their symptoms are different, their common characteristic is that the ducts of the cotton plants appear brown in color (the color of cotton plants affected by fusarium wilt is darker).

There are mainly three factors causing the development of fusarium and verticillium wilt in cotton: first, there are definite number of pathogens; second, cotton varieties that are senstivei to the diseases are planted; third, the environment is suitable for the occurrence of the diseases. The suitable temperature for pathogens is about 25 degrees centigrade. In field observations, the peak period of occurrence of fusarium wilt is before or after the square of cotton emerges. Verticillium wilt beings when the plant has 4 or 5 true leaves and develops rapidly after the square emerges. The peak period of occurrence is during the boll-forming period.

The paths of propagation of fusarium and verticillium wilt of cotton are complex. As soon as they are propagated into the cotton fields, it is very difficult to eradicate them, and the consequences are severe. Bacteria-carrying cotton seeds are the initial source of propagation of fusarium and verticillium wilt diseases over long distances. Each cotton region should strengthen inspection when transporting cotton seeds before spring sowing to cut off this path of propagation. In the cotton fields, these two diseases can be spread by the roots, stems, branches, leaves of diseased plants, their cotton seed cakes used as fertilizers, the cotton waste of their cotton seeds, and water used for irrigation by channeling along furrows. Attention should be given to this in planting.

Fusarium and verticillium wilt of cotton were once regarded as "incurable diseases". Many years of prevention and control have proven that strengthening plant inspection, strictly protecting disease-free regions, planting disease-resistant varieties, gradually improving severely diseased regions, emphasizing rotational cropping and reverse cropping, reducing slightly affected regions, utilizing effective chemicals to eradicate diseased plants and diseased spots, eliminating scattered diseased regions and such comprehensive measures of prevention and control all produce notable results.

STATE COUNCIL ISSUES NOTICE ON PREVENTION OF COTTON DISEASE

Beijing RENMIN RIBAO in Chinese 7 Mar 82 p 2

[Article: "State Council Issues Notice to Localities Listing Five Ways To Prevent, Control and Inspect Fusarium and Verticillium Wilt Disease of Cotton"]

[Text] The State Council recently issued a notice calling on localities to do a good job of preventing, controlling and inspecting fusarium and verticillium wilt diseases of cotton.

The notice says: fusarium and verticillium wilt are two destructive diseases of cotton. The seriously affected cotton plants wilt and die and cease to produce. In slightly affected plants, the yield is affected, and the length strengh and grade of fibers and such inner qualities are affected. This type of disease can be spread to distant places by seeds. Once the diseases are introduced, the germs can exist for a long time in thl soil and they are difficult to eradicate. The notice says: to guarantee the safety of our nation's cotton production, the following measures must be taken concerning the inspection, prevention and control of fusarium and verticillium wilt diseases of cotton:

1. Propaganda work must be carried out well so that the leadership and the masses in cotton-producing regions fully recognize the seriousness of damage by fusarium and verticillium wilt of cotton and the great significance of inspecting and treating the seeds well.

2. Before this spring's cotton sowing, the agricultural departments of each cotton-producing province, city and autonomous region must soncsientiously inspect the cotton seeds shipped from the diseased regions and disinfect seeds that may be carrying the diseases.

3. During the growth period of cotton, we must organize forces to survey the occurrence of the diseases in a key way on the basis of plans. On the basis of surveying and research, the severely diseased regions, the slightly affected regions and scattered regions where the diseases have occurred, should be clearly marked. In the severely diseased regions, popularization of disease-resistant varieties should be the main effort of comprehensive

prevention and control. In slightly affected regins and scattered regions of the disease, diseased plants must be removed in time to destroy the points of disease and to control spreading. To protect the disease-free regions, in the future, cotton seeds shipped into disease-free regions must be inspected by plant inspection departments and they must be disinfected and then popularized. Without approval by the plant inspection departments, seeds are not allowed to be popularized in disease-free regions. Those who violate inspection rules must be subjected to criticism and education, the economic responsibility must be pursued, and the cases must be handled strictly.

4. The cotton seed management system must be made sound. Bases for the propagation of superior varieties of disease-free cotton must be established, and inspection work at the production localities must be strengthened. In the future, propagation and popularization of cotton varieties and management and adjustment must be uniformly managed by the seed departments. Scientific research units cannot distribute at will new varieties which have not been evaluated and determined. When arranging new varieties for expanded experiments, approval by the plant inspection departments of the local province, city and autonomous region must be obtained.

5. The nation's scientific research coordination group on fusarium and verticillium wilt diseases of cotton must include in the key scientific research projects the selective breeding of new high-yielding and superior quality varieties that are concurrently resistant to fusarium and verticillium wilt diseases, and they must also include the study of techniques of disinfecting seeds and soil.

BENEFITS DERIVED IN SETTING BASE PROCUREMENT, ALLOCATION FIGURES

Beijing ZHONGGUO CAIMAO BAO in Chinese 26 Jun 82 p 1

[Article: "Zhejiang Sets Base Figures for Procurement and Allocation of 14 Products, Strengthens Planning For Production and Purchase of Major Agricultural and Sideline Commodities"]

[Text] Zhejiang Province has instituted base procurement figures and base allocation figures for 14 major category II agricultural and sideline products in a program whereby the planned economy is paramount and market regulation supplementary. These will be put into effect in the production and procurement of agricultural and sideline products to promote the stable development of agricultural and sideline production and to increase quantities procured by the state.

During the previous period, in the sale to the state of agricultural and sideline products, some places in Zhejiang Province exhibited concern only for partial interests and overlooked the trend in state plans. Some of the agricultural and sideline product processing plants they operated themselves took raw materials away from some state industrial plants, impairing effectiveness in utilization of agricultural and sideline products. In some cases, before sales to the state of major agricultural and sideline products were fulfilled, goods were sold elsewhere thereby hurting fulfillment of state purchasing plans. In accordance with the spirit of the practice of centralized purchasing and quota purchases of category I and II agricultural and sideline products, and in accordance with the great or small importance to the national economy and the people's livelihood of different products, the Zhejiang Provincial People's Government studied the production and procurement situation for individual products, and in 1980 set base procurement figures or proportional procurement and retention figures for category II agricultural and sideline products including tea, silkworm cocoons, jute, citrus fruit, lumber, moso bamboo, maogao bamboo [3029 4643 4554], tung oil, Chinese tallow tree seeds, sugar, aquatic products, rosin, grass mats, and raw lacquer. While adhering to institution of a policy of centralized purchasing and quota purchases of major agricultural and sideline products, the requirements of the situation as a whole should be properly linked to the self-determination of production units and peasants to assure basic needs of the national economy and the livelihood of the people, with an exchange of commodities across jurisdictional lines.

As regards major agricultural and sideline products for which development of production is fairly stable, they set base procurement figures while also setting base allocation figures. For agricultural and sideline products in excess of base figures, they differentiated circumstances and adopted the following several methods:

(1) For traditional mainstay commodities such as tea and silkworm cocoons they instituted a division of excess and an increased price for excess procurement. In the case of tea, for example, the base procurement figure for the province was 1.1 million dan, and the base allocation figure for unfired tea leaf was 1.04 million dan, guaranteed to remain unchanged for 5 years. Sixty percent of tea leaf production in excess of base figures was centrally purchased by supply and marketing cooperatives, and 40 percent was handled by communes and brigades. After fulfilling quotas, production units could sell the remainder themselves and could, with permission, transport it elsewhere for sale. Production unit and commune member sales to the state of tea in excess of base figures brought higher prices. The increased price paid production units and commune members by dealer units was derived from a reduction in industrial and commercial taxes levied. Profits from the refining of unfired tea leaf from tea producing counties to state tea refining plants in excess of allocation figures are to be divided on a 30-70 basis, i.e., 30 percent being retained by the tea refining plant and 70 percent reverting to the county making the excess allocation for use in development of tea production.

(2) For industrial raw materials in extremely short supply within the province such as rosin, there is to be centralized procurement and increased price bonuses. The province's base procurement figure for rosin is 3,750 tons; it is 120,500 dan for pine resin 80 percent of which is to be allocated by the province with no change guaranteed for 3 years. For quantities in excess of base figures handled by communes and tree farms, a profit of 2 yuan per dan of pine resin is to be paid by processing plants for sales in excess of base figure. In the case of counties providing rosin in excess of base figures, the province will provide a subsidy of 800 jin of nitrogenous fertilizer and 250 jin of unprocessed food grain per ton of excess rosin sold. It will also allocate and sell industrial goods for use in daily life at a value equal to the resin.

(3) Where demand is limited, production in excess of base figures will be purchased at list price. One example is jute for which purchases at list price have been set at 2.55 million dan and purchases at negotiated price set at 450,000 dan with centralized allocation by the province guaranteed without change for 5 years. Jute in excess of 3 million dan will revert to procurement at list price.

(4) Where changes in the market supply and demand situation are unpredictable, purchases will be made at fluctuating prices. In the case of straw mats, for instance, the province's base procurement figure is 5.13 million mats centrally allocated by the province with no change guaranteed for 3 years. For quantities in excess of the base figure, supply and marketing

cooperatives will make purchases at fluctuating prices or else act as a purchasing and marketing agent.

In cases in which output is very unsteady or quantities purchased very small to begin with, or where active development of agricultural and sideline products is in process, they will set purchase and retention proportions and proportions to be purchased at list price and negotiated price.

In the process of setting base procurement figures, Zhejiang Province both gave attention to concurrent concern for the welfare of the state and peasants, and gave attention to concurrent concern for the interests of prefectures, municipalities, and counties as well as to concurrent concern for the welfare of commune and brigade enterprises. Every item was discussed by pertinent planning, agricultural, industrial, finance and trade, and commodity pricing department, and after a unanimous opinion was obtained, only after submitting the matter to the Provincial Government Standing Committee for discussion and approval was it handed down for implementation. Thus there was rather good concurrent concern for the interests of the country, collectives, and individuals, and for the interests of all departments. Though not tried for very long, and though some methods are still being steadily improved; nevertheless, during the past 2 years some initial benefits have been obtained. First of all the country's basic needs have been guaranteed. In recent years procurement of Zhejiang's tea, silkworm cocoons, and hemp has increased, the fundamental needs for state industrial plant production being assured. The shortages of commodities in some markets have also been ameliorated from what they had been for the previous several years. In addition, both production and procurement are more planned. In the case of moso bamboo and silkworm cocoons, for example, after the state had set base procurement figures, all production areas instituted quotas on production units, and all production units made specific arrangements about production in turn. After fulfilling plan, production units could arrange production on the basis of market demand and production, thereby reducing blindness in production. In procurement too, the situation was changed from formerly when whatever was produced was purchased, helping assure the country's basic needs. As a result of the development of production, both the country and the peasants have increased their earnings. In 1980 after the peasants had overfulfilled base figures for sales to the state, as a result of increased prices or negotiated prices paid in the process of procurement, earnings increased directly or indirectly by 70 million yuan. In 1981, they increased further to 80 million yuan. As far as national earnings are concerned, though the state reduced taxes to increase profits when buying products in excess of base figures and used some revenues to subsidize the peasants; nevertheless, as a result of the growth of production, once procurement had increased, the amount that the state took back in industrial and commercial revenues as a result of processing and sales amounted to more than the subsidies provided the peasants. Take tea for example. As a result of increasing profits through reduction of taxes last year, the state bought 466,000 dan of tea in excess of base figures. A rough preliminary calculation shows that as a result of the processing and sale of this tea, industrial and commercial tax revenues increased by more than 60 million yuan. After deducting the somewhat more than 24 million in taxes, allowed as profits for peasants, the state realized increased tax revenues amounting to about 40 million yuan from the processing and sales links.

BRIEFS

TYPHOON 11 WARNING--The Central Meteorological Observatory at 0600 [2200 GMT] on 7 August issued the following typhoon warning: At 0500 on 7 August, the center of this year's typhoon No 11 was located in the Pacific approximately 350 kilometers southeast of Hengchun Municipality, China's Taiwan Province--20.9 degrees north latitude and 124 degrees east longitude. Winds near the center increased to wind force 11 to 12. At present, the typhoon is moving west-northwesterly at a speed of about 10 kilometers per hour. It is expected to continue this course and to gradually approach the coastal areas of our country's Taiwan Province. It may land in southern Taiwan's coastal areas between tonight and tomorrow morning. Then, it will move toward Fujian Province's coastal areas. As a result of the typhoon, winds will gradually increase to wind force 6 to 8 in the Pacific east of Taiwan, Taiwan Province, the Bashi Channel, the Balintang Channel, the Taiwan Straits as well as Fujian's and eastern Guangdong's coastal areas between today and tomorrow. In the areas of or near the course of the typhoon's center, winds will range from wind force 10 to 11, and there will be heavy or torrential rain. All units are asked to listen carefully to local weather forecasts. [Text] [OW071055 Beijing Domestic Service in Mandarin 2230 GMT 6 Aug 82]

BRIEFS

EARLY RICE HARVEST--According to an estimate on 16 July, Fujian Province has already harvested more than 1.1 million mu of early rice. The single crop output of the six prefectures and cities of Sanming, Jinjiang, Putian, Longyan, Xiamen and Longxi has increased over the same period in 1981. However, because of an overall delay in ploughing and planting this year in various locations, and also because there were more rainy days and fewer sunny days in the month of June, the early rice maturing period had been delayed this year. As a result, harvest progress was slower than the same period in 1981. Prefectures and cities such as Jianyang, Fuzhou, and Ningde all had reduced output compared to the same period last year due to disasters like flooding and rice blast disease. Jianyang Prefecture harvested more than 150,000 mu of early rice, a decrease of 108 jin of yield per mu compared to this time last year. [Fuzhou FUJIAN RIBAO 22 Jul 82 p 1]

SUMMER GRAIN PROCUREMENT--The Gansu Provincial People's Government held a telephone conference on 3 August urging governments at all levels to strengthen leadership over the summer grain procurement and storage work. Xu Feiqing, deputy governor of the province, presided over the conference. This year the province will reap a better harvest of summer grain than last year. It is estimated that the total yield will increase by some 10 percent. [SK062212 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 5 Aug 82 SK]

PROVINCIAL CCP COMMITTEE FIRST SECRETARY SPEAKS ON RURAL PROBLEMS

Guangzhou YANGCHENG WANBAO in Chinese 20 Jun 82 p 1

[Article: "Perseverance in Diverse Forms of Agricultural Production Responsibility Systems Is Emphasized by Ren Zhongyi [0117 0112 1138] at Provincewide Prefecture CCP Committee Agricultural Secretaries Conference. Rural Work at the Present Time Should Preserve 'Three Consistencies,' Give Attention to the 'Three News,' Take Firm Hold of the Building of the Party's Grassroots Level, and Intensify Building of Spiritual Civilization"]

[Text] Guangdong CCP Committee First Secretary, Ren Zhongyi said recently at a conference of Prefecture CCP Committee agricultural secretaries studying new conditions, and new problems in the wake of institution of agricultural production responsibility systems and the study of how to go about giving further forward impetus in future to agricultural work in Guangdong Province that the CCP Central Committee had repeatedly emphasized its intention to institute policies of liberalization toward foreign countries and to enliven the economy internally. Institution of diverse forms of agricultural production systems is firm and unshakeable.

Comrade Ren Zhongy noted that the key to whether or not we are able to be "firm" in this way in our work lies in how we handle the new problems that appear following institution of these policies. For example, following institution on responsibility systems in agriculture, had the new problems that appeared been ignored rather than diligently solved, or had these problems been overly exaggerated to bring about an actual negation of these policies and a retrogression away from them, then "firm" would have become empty talk. Conscientious study of new conditions, and genuine solution of new contradictions and new problems, plus unswerving carrying out of the line, program and policies of the Third Plenary Session of the 11th Party Central Committee with positively no wavering at all is something that we must be extremely attentive in mastering in our rural work and in all work. Therefore, all jurisdictions must diligently study and spread the representative experiences introduced at this conference. However, in studying and spreading them, one must proceed from one's own realities without copying mechanically in disregard of specific conditions.

In speaking about current rural work, Comrade Ren Zhongyi emphasized first the preservation of the "three consistencies."

First is consistent policies. Agriculture depends on policies, both on policies that are accurate and on policies that are consistent.

Second is consistent production responsibility systems. In deciding just which form of a responsibility system to adopt, each place has to adapt general methods to local situations. The leadership has to give tailored guidance to different areas. Consistent responsibility systems and perfected responsibility systems are one and the same; they have to be perfected in order to be more consistent.

Third is a consistent grain growing area. No further reductions can be made in Guangdong Province's grain growing area, particularly in its rice growing area; it must remain consistent at existing levels.

Comrade Ren Zhongyi noted that simultaneous with implementation of the "three consistencies," adroit guidance according to circumstances had to be provided, with attention given the "three news" as follows:

First is the spread of new techniques.

Second is organization of new combinations.

Third is the opening of new fields of production.

Comrade Ren Zhongyi emphatically pointed out the need to take firm hold of the building of the party at the grassroots to lay a good foundation for development of all endeavors. This is an assurance for achievement of the three "consistencies," and attention to the "three news," it is also an assurance for doing all rural work, and for building new socialist rural villages.

Comrade Ren Zhongyi also pointed out that rural villages also had to strengthen the building of socialist spiritual civilization including development of rural cultural, educational, sanitation, and athletic endeavors. The peasants should be educated in socialism, patriotism, and collectivism, and educated in concurrent concern for the three [country, collective, and individual]; routine ideological and political work should be intensified; prevailing habits and customs should be changed; and a campaign of five cares and four beautifications should be launched, etc.

This provincewide Prefecture CCP Committee Agricultural Secretaries Conference convened by the Provincial CCP Committee was held in Guangzhou from 10 to 18 June.

CSO: 4007/475

REVISION OF LATE RICE CROP PLANTING PLANS URGED

Guangzhou NANFANG RIBAO in Chinese 14 Jun 82 p 2

[Article: Need for Attention to Readjustment of Crop Patterns for Late Crop Varieties in View of Expected Delay in Ripening of Early Rice Crop"]

[Text] Recently the Guangzhou Municipal Agriculture Committee held a conference on rice production in Panyu County. Agricultural experts and comrades from agricultural departments attending the conference analyzed this year's early crop production situation and advised the following: Inasmuch as ripening of the early crop will be later this year than in former years, action must be taken at once to readjust crop patterns for late crop varieties in order to make the most of advantages and avoid disadvantages to win a bumper harvest from the last crop.

Provincial units concerned report that this is a general problem throughout the province that must be accorded a high degree of serious attention. This is because, first of all, as a result of the return of cold spring weather that hurt this year's early crop, in many of the province's prefectures sowing and transplanting was done later than in former years. In Guangzhou Prefecture the delay was from 7 to 10 days. Second, temperatures were not high during the "vegetative growth stage" following transplanting and before the differentiation of young panicles. Statistics from the Tianhe Station of the Provincial Meteorological Observatory show that during the 70 day period from March to early May, total cumulative temperatures were 136 degrees less than during the same period last year. For the 40 day period during April to early May, total cumulative temperatures were 109 degrees less than for the same period last year. Early rice is a temperature sensitive variety, and when cumulative temperatures are insufficient, the period of young panicle differentiation is delayed and the ripening time may be delayed too. Third, in many places the number of late ripening varieties in the early crop are numerous. In Guangzhou Prefecture rural villages, for instance, they account for about 65 percent of the total crop, an all-time high year. Fourth, more rain than usual fell during late May and June, and there was less sunshine than usual. All these factors have made for delayed ripening of the early crop this year as compared with former years, producing a great impact on the late crop production season.

Analysis in terms of historical circumstances also merits attention. Post-liberation historical records show that years with a return of coldness in the spring are years when possibilities for a bumper harvest from the early crop are fairly great, while the late crop is prone to reduced yields. This is because when a return to cold in spring occurs during the early crop, the ripening time for the early rice will generally be delayed. If the late crop contains too many late ripening varieties, or if it is not transplanted just when it should be, the late rice crop will be unable to avoid the cold dew winds or cold damage, which will result in reduced yields.

This year Guangdong Province's early rice has again been fairly seriously stricken with a return of cold weather in spring. It is recommended that all jurisdictions decide at once to promptly readjust their crop patterns for late rice varieties, making appropriate cutbacks in the area planted to late ripening varieties and increasing the area planted to early and intermediate ripening varieties. Comrades attending this conference also emphasized that in places practicing responsibility systems whereby output quotas are fixed on a household basis and whereby peasant households assume full responsibility for task completion, because many peasants lack knowledge about scientific farming, leaders at all levels are to do good ideological work, explain reasons, and help with the proper matching of late crop varieties. All jurisdictions should promptly allocate seeds from places with surpluses to places with shortages, and rapidly organize their movement to places where they are needed to satisfy urgent peasant needs. In addition, preparatory work of other kinds should also be done, as for example, all around inspection and repair of all kinds of farm machines and implements, further implementation of plow oxen responsibility systems, protection of draft animals, attention to transportation of fertilizer reserves, and prompt movement into places where they are needed. Only in this way can there be any assurance that late rice crop transplanting tasks will be completed before the proper farming season has passed for the winning of a bumper grain harvest for the year as a whole.

PLASTIC MULCHING OF SUGARCANE PROMOTED

Gaungzhou NANFANG RIBAO in Chinese 14 Jun 82 p 2

[Article by Wang Jianming [3769 7003 2429], director Sugarcane Institute, Ministry of Light Industry: "New Technique of Plastic Mulching Sugarcane Being Promoted in Province Has Great Prospects"]

[Text] Though China did not invent plastic mulching, its use has developed very rapidly in China, and it is used in extraordinarily ingenious ways. Following a visit to China, American professor Weitewaer [phonetic] said in a report to the American Department of Agriculture as follows: The things that the Chinese People's Republic are studying in the field of agricultural science are very numerous, one of which is creative development of agricultural applications of plastic mulching.

The plastic mulching of sugar that Guangdong Province is promoting as a new technique has great prospects. This is because every year in the cane producing regions of the province serious winter and spring drought seriously threaten the winter growth of seedlings of early maturing cane that have been left in the ground, and of the dormant roots of early maturing varieties, with the result that early maturing varieties reproduce slowly. This means that neither the early maturation characteristics nor the high sugar properties of early maturing varieties can come to the fore, and thus the large expenditure by the state on preferential subsidies for early maturing varieties are wasted, with no noticeable increase in sugar during the early cane crushing season. If plastic mulch is used to cover winter-planted early maturing sugarcane, and if plastic mulch is used to cover the dormant roots of early maturing sugarcane, this problem can be pretty well solved. Furthermore, the coastal saline field sugarcane growing area, which constitutes a substantial part of the area of the province, is in danger from salt damage even on sunny days. If plastic mulch is spread between sugarcane rows before the rows grow shut at some time between planting and the seelding stage, not only will weeds be reduced between rows, but capillaries in the soil will also be prevented from bringing water to the surface, and increase in the salt content of the soil surface will thereby be controlled.

The new technique of covering sugarcane with plastic mulch helps all cane growing more canes and to increase their sugar content. It helps improve sugarcane farming methods to meet sugar refinery production requirements, so it greatly helps both industry and agriculture. For example, it has played an active role in increasing both cane output per mu and earlier ripening of the autumn planted sugarcane that was promoted for cultivation during the 1970's. However, as a result of the 14 to 15 month growing season required for fall planting sugarcane, the soil utilization rate is fairly low. Currently, not only in the Pearl River delta and the Hanjiang Delta, where land is scarce relative to population, has the cane growing area declined, but even in the Zhanjiang cane growing area, where land is relatively abundant in terms of population, the same trend had occurred. (In Xuwen and Haikang counties, for example, the fall planted cane area now amounts to only one one-thousandth and three one-thousandth of the total area planted to sugarcane. Were the new farming techniques of fall propagation of seedlings with winter and spring transplanting to be used (plastic mulching used during the periods of low temperature in winter and spring), the cane would have an open field growing season of about 11 months, and virtually the same benefits could be obtained in terms of cane yields per mu and high yields of sugar from the early crop as from the growing of fall sugarcane.

In addition, in high altitude cane growing areas where frost and freezes occur, frost and freezing shorten the sugarcane growing period with the result that the cane frequently does not mature sufficiently, the sugar content of canes tends to be low, and yields are limited. In such cane growing areas, sole use of early maturing high sugar varieties is not enough. If plastic mulch is used to cover winter planted or early spring planted cane, the growing season can be extended, resulting in both an increase in cane yields per mu and an earlier ripening season. In addition, by using plastic mulch to cover dormant roots in cane growing areas where frost and freeze would damage dormant roots left in the soil, thereby establishing a local dormant root system of cane growing, losses from storage of varieties could be avoided. Even in cane growing areas without frost and freezing, dormant roots may be covered with plastic mulch to lengthen the number of years dormant root sugarcane will live, to increase output from dormant root sugarcane, and to cause earlier ripening of dormant root sugarcane, (preliminary experiments show cane sugar content can be increased by an absolute 1.5 percent) thereby gradually reducing sugarcane production costs and gaining the initiative in management of sugarcane production.

Were plastic mulching of sugarcane promoted generally, economic benefits would increase strikingly, particularly since dryland sugarcane in Guangdong Province accounts for more than 70 percent of the total sugarcane growing area, with most of the sugarcane growing area sustaining serious winter and spring drought, including some sugarcane areas where water conservancy conditions are very poor and not readily improvable. Formerly, it was impossible to use growing of seedlings in winter for spring planting during dry periods in such sugarcane growing areas, and by the time the rainy season had come, the crushing season was finished. If one wanted to get seedlings for summer planting, there were no seedlings to be had. In addition, roots of dormant sugarcane, when taken up during winter or early spring, also suffered from a great loss in vitality as a result of sustained drought. During the following year not only were they slow to put forth shoots, but shoots did not grow evenly and yields were very low. Were winter and spring grown sugarcane directly planted and covered with plastic mulch, or were seedlings being grown in nutrient pots covered with plastic mulch for transplanting during the time of spring rains in the succeeding year, and were dormant sugarcane roots also covered with plastic mulch, the growing season for spring sugarcane would be advanced, and both yields per mu and sugar content would be increased. Furthermore, the threat from winter and spring drought to newly planted sugarcane would be reduced. Such a method of combating and preventing drought is more realistic than simply carrying out spray or drip irrigation, and is also more active than waiting for particularly drought resistant varieties to be bred.

At the present time some cadres and masses fear that mulching of sugarcane may increase production costs and reduce earnings. Practice in pilot project units has demonstrated that such apprehensions are unnecessary. Take the case of the Xiaxue Production Team in Yanggongzhou Production Brigade, Shatian Commune, Dongguan County, for example. In mid-January this year, they used 200 kilograms of plastic mulch to cover 27 mu of dormant root sugarcane for a month, after which this same plastic mulch was again used to cover 30 mu to promote sprouting of spring sugarcane that had been planted. The average cost for plastic mulch was only 13 yuan per mu, equivalent to the price paid for 171 kilograms of Yuetang 57/423 sugarcanes, or 143 kilograms of Guitant No 1 sugarcanes. Even if the cost of plastic mulch for dormant root sugarcane were 30 yuan per mu, that would not be more than the price of 450 kilograms of sugarcanes. Meanwhile, during the past 2 years, wetland dormand root sugarcane grown at plastic mulch pilot project units produced at a rate of increase of between 0.5 and more than 1 ton per mu. For example, our institute experimented with plastic mulching of dormant root sugarcane in fields surrounding the institute, and even though mulching was delayed until March, sugarcane output increased from somewhat more than 15,000 jin to somewhat more than 19,000 jin, an increase of 19 percent. At the Zhanjiang Sugarcane Experimental Station, sugarcane grown on hill drylands was plastic mulched at the end of March last year for an increase in output as high as 30 percent. Thus, the increase in sugarcane yields more than offsets the cost of the plastic mulch, and since the mulch increases the sugar content of the cane and hastens maturity, this translates into added income.

Plastic mulching of sugarcane in combination with the culturing of cane seedlings in nutrient pots is without doubt a major technical measure for increasing sugarcane output and increasing sugar in Guangdong Province. However, inasmuch as not much time has elapsed since introduction of this technique into the province, it has to be rapidly promoted for use throughout the province's sugarcane growing areas, which will require efforts by all concerned. In addition to doing a good job in setting up pilot points to provide demonstrations, intensifying research, and conducting publicity, appropriate bonus policies should also be adopted. At Shatian Commune in Dongguan County, plans call for an increase next year in the sugarcane area mulched with plastic to 5,000 mu. Payment for the plastic will be made from a loan from the Peasant's Bank arranged for by sugar refineries concerned in the county, who will be responsible for paying interest to the bank. Except for the cost of the plastic, all or most of resulting increase in earnings will go to communes and brigades. Other jurisdictions should note their method.

BRIEFS

EARLY RICE HARVEST--Guangdong Province has reaped a record harvest of early rice and an increase of 700 million jin is expected. Apart from Shaoguan Prefecture and the seriously flooded areas, all counties have increased production output in varying degrees. There were many natural disasters this year. In spring, there was plenty of rain and the temperature was very low. In May, heavy rain fell in Qingyuan, Yingde, Guangning and Sihui counties and there were maintain torrents. Some 2.5 million mu of early-crop fields were flooded, of which, some 600,000 mu were damaged. Despite natural disasters, the province was able to reap a harvest of early crops due to the implementation of the production responsibility system. Furthermore, some 30,000 peasants had signed technological contracts with technological departments, which has improved the standard of scientific planting. BRIEFS

LOW-YIELD LAND IMPROVEMENT--The Guangxi Regional Agricultural Bureau allocated 20,000 tons of chemical fertilizer to 120 communes to improve 2 million mu of low-yield farmland. The regional agricultural bureau held a meeting with the directors of the prefectural and county agricultural bureaus to form a policy to make good use of chemical fertilizer so as to strive for a bumper harvest of late rice. [Nanning Guangxi Regional Service in Mandarin 1130 GMT 14 Jul 82 HK]

EARLY RICE PRODUCTION--Guangxi region reaped a bumper early rice harvest. According to preliminary statistics, the region's total output of grain up to the present is 800 jin more than in the corresponding period of last year. Output of peanuts, rapeseeds, flue-cured tobacco, tea, cocoons, pineapples and bananas has shown relatively great increases. The number of communes throughout the region which are commercial grain bases has increased from 150 in 1980 to 197 this year. The arable land area accounts for 41 percent of the entire region's arable land area. With the vigorous support of relevant departments, the development of grain production in the region has been promoted. [HK100950 Nanning Guangxi Regional Service in Mandarin 1130 GMT 4 Aug 82 HK]

TECHNIQUES OF CULTIVATING COTTON SEED 'LUMIAN NO 1' GIVEN

Shijiazhuang HEIBEI RIBAO in Chinese 13 Mar 82 p 2

[Article by the Economic Crops Department of the Provincial Bureau of Agriculture: "Discussion on One-Time Sowing and Preserving Full Seedlings of Cotton--Supplement to the Article 'The Techniques of Cultivating Lumian No 1'"]

[Text] In the article "The Techniques of Cultivating Lumian No 1" published on 1 March, the section on "striving toward one-time sowing to preserve full seedlings" pointed out the necessity to select the appropriate sowing time. In addition, the following must also be done:

1. The density must be appropriate and the structure of the colony must be rational. Lumian No 1 has a strong boll-forming characteristic. It has more summer bolls, the potential of the individual to increase yeild is great, and the plant consumes a lot of organic matter. To obtain high yields, many ways must be used to create conditions for the plant to manufacture organic substances. The most important way is to solve the problem of light. If the problem of light energy is solved well, the variety's characteristics will be able to develop, and thus higher yields can be obtained. Therefore, we must not unilaterally emphsize dense planting of small plants. At present, the problem in large area production is that the row distance is overly close, and missing seedlings and broken ridges are serious. When the row distance is too close, not only is field management inconvenient, but in rainy weather this causes the formation of a canopy in the cotton field. Boll forming on the middle and lower parts of the plant is poor, the number of rotten bolls increases, and this leads to reduced yields. If the row distance is slightly larger, then during years of drought, sometimes the cotton plants will not close up the ridges tightly, and because aeration and light penetration are better, the middle and lower parts form more bolls, the weight of the bolls increases, the quality of cotton is better, and there will not be large losses. A relatively more rational structure of the colony of Lumian No 1 is: a plant height of 1 meter and a per-mu yield of about 180 jin of ginned cotton, a row distance of 2.5 chi, a distance of 8 cun between plants, and an actual harvest per mu of about 3,000 plants; a plant height of 80 centimeters, a per-mu yield of ginned cotton of 100 to 120 jin, a row distance of 2.2 chi,

a distance of 7 cun between plants, and an actual harvest per mu of 3,500 to 4,000 plants; a plant height of 60 centimeters, a per-mu yield of ginned cotton of 80 to 100 jin, a row distance fo 2 chi, a distance of 6.5 cun between plants, an actual harvest per mu of 4,500 plants; a plant height below 60 jin, a row distance of 1.6 to 1.8 chi, a distance of 6 cun between plants, an actual harvest per mu of 5,000 to 6,000 plants. With such row distances, should we use large and small rows or equidistant rows? We can follow local custom; we should not forcefully practice uniformity. In general, if the average row distance is over 2.3 chi or under 1.8 chi, equidistant rows would be better. If the average row distance is about 2 chi, it is suitable to use large and small rows.

. The seeds must be treated well. To shorten the time the cotton seeds have to remain in the soil, the seeds must be treated at the time of sowing so that the cotton seeds are in a state ready for germination. Sowing should be carried out when about 20 percent of the cotton seeds have reached the stage of pouting and budding.

There are many ways of treating cotton seeds. A good method is the following: On the morning of the first day, the cotton seeds should be soaked in hot water that has been "boiled three times and left to cool once" or "boiled two times and left to cool once" for half an hour, or the seeds can be directly soaked in cold water for 48 hours until the cotton seeds absorb sufficient moisture, the pericarp of the seeds softens, and the cotyledon separates into layers. The seeds are then taken out and dried under the sun for a while until the short cotton lint becomes white. Then, the cotton seeds are piled up overnight into a level pile of one and a half chi or two chi for stewing to stimulate germination until about 20 percent of the seeds begin pouting. Now, they are ready for sowing. When using Furandan granules to mix with the seeds, the chemical can be mixed with the seeds after forced budding. Each mu of cotton seeds can be mixed with 4 to 5 jin of 3 percent Furandan.

3. Selecting an appropriate sowing method. Each locality must determine an appropriate sowing method according to the local moisture condition, the condition of the seeds and the custom. Generally, it is better to use machine sowing or exposed sowing. It is better to use furrow seeding in saline and alkaline soil. In dryland where the moisture condition is poor, sowing by deep drilling to lift up the soil or dibbling with water can be carried out. Regardless of which sowing method is used, some reserve seedlings must be planted on the sides of the fields or on the backs of ridges to prepare for transplanting and replacing missing seedlings.

4. After sowing, management must be strengthened in time. Attention must be paid to inspecting each ridge and each parcel of land, and when problems are discovered, they should be solved in time. If the weather is arid and there is a lot of wind, if the moisture condition of the soil deteriorates, if there is a danger of the seeds drying up, packing to

improve moisture in the fields where bottom moisture conditions are good should be undertaken to improve the water supply in the seed layer. When the bottom moisture condition is poor, a small amount of water can be irrigated along the ridges with a small water kettle so that the water will gradually percolate to the cotton seeds. If little rain occurs after sowing, the hard covering layer of the ground should be broken up in time. If heavy rain occurs, the ground should be harrowed deeply for aeration to help the seedlings emerge from the soil. Harrowing should be as deep as the sowing depth. When the seedlings emerge in rows, the soil should be intertilled and loosened in time to bring out the moisture, to preserve bottom moisture and to stimulate the growth of the seedlings.

HEILONGJIANG

BRIEFS

QINGGANG COUNTY FARMING--Qinggang County, Heilongjiang Province, takes advantage of the opportune time after the rain to plant grain crops, vegetables and forage grass. Though stricken by drought and insect pests this year, the county still plans to plant 13,000 mu of buckwheat, 24,000 mu of vegetables and 53,000 mu of forage crops. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 21 Jul 82 SK]

FIELD MANAGEMENT--Yilan County in Heilongjiang Province is vigorously strengthening field management to cope with natural disasters and try to improve poor growth of seedlings. There are over 400,000 mu of crops across the county, which have been damaged in varying degrees by insect pests. Therefore, the county has dispatched over 100 tractors to join the extra operation of weeding, plowing and banking soil to poorly growing crops. The county has planted vegetables over its 70,000 mu farmland whose former crops were totally damaged by the drought and insect pests. [SK190010 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 17 Jul 82 SK]

SURFACE WATER SURVEYING--Through 3-year efforts, hydrogeological technicians in Heilongjiang Province have worked out statistics on provincial surface water sources. Over the past many years, the province's per year precipitation was 531 mm. Its per year evaporation volume is 391 mm, and its per year surface water resources total 655.81 centimeters. [SK302244 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 29 Jul 82 SK]

WHEAT HARVESTS--Farms in land reclamation areas throughout Heilongjiang Province have begun their harvesting operation. As of 20 July, they had harvested 905,000 mu of wheat crops and threshed 417,000 mu of wheat crops, obtaining about 64.5 million jin of net wheat. MEASURES SPECIFIED TO PREVENT WHEAT DISEASE

Jiangsu XINHUA RIABO in Chinese 2 Mar 82 p 2

[Article: "Pay Attention to the Prevention and Control of Pellicularia Gramineum Ikata et Matsumura"]

[Text] Cadres and commune members in farm villages know very well about the damage of sheath and culm blight of rice, but they are relatively unfamiliar with Pellicularia gramineum Ikata et Matsumura, which urgently needs attention.

According to observations and measurements by the Zhengjiang Prefecture Agricultural Science Institute from 1979 to 1981, Pellicularia gramineum Ikata et Matsumura is caused by the rhizoctonia fungus. In recent years, it has appeared on several popularized varieties in Zhengjiang Prefecture. It has spread relatively quickly and its damage is relatively serious. The Dantu County Agricultural Bureau investigated 504 parcels of wheat fields and found that the number of severely diseased parcels reached 9.3 percent. In 1981, Wujin, Jintan, Lishui, Gaochun, Yangzhong Counties surveyed 397 small parcels of wheat fields and found that the average number of diseased plants reached 25.7 percent.

The Pellicularia gramineum Ikata et Matsumura and sheath and clum blight of rice are notably different regarding the time of occurrence. Sheath and culm blight of paddy rice generally begins during the tillering period of paddy rice. Wheat is affected by Pellicularia gramineum Ikata et Matsumura during different stages of growth; thus we find rotten buds, dead seedlings, diseased seedlings, rotten stalks and flower stems, and wilted bearing spikes. Wilted bearing spikes or lodging caused by the rotting of flower stems seriously affect the yield. Rotting of flower stems is characterized by the occurrence of light brown diseased rhombus spots on the lower leaf sheaths, generally after the wheat seedlings have returned green. As the temperature rises and the whest seedlings joint, the base of the leaf sheath first produces waterlogged elliptical spots, then greyish cloudy diseased spots appear on the central part and light brown cloudy diseased spots occur at the edges. This is called "mosaic stalk." Afterward, in rainy and highly humid weather, white or yellowish-white layers of hypha can be seen on the inside of the diseased leaf sheath and the stalks. When the germs of the leaf sheath affect the stalks, short light brown striped spots first emerge and then they expand into rhombus spots (called eye spots). When the diseased spots on the stalks enlarge and connect and spread over the entire internode, frequently the wall of the stalk softens, causing physiological loss of water and the plnat dies from necrosis, or the diseased parts split open longitudinally and the wheat plant withers prematurely. Mosaic stalks and rotting stems prevent some plants which could form spikes originally from forming spikes, or cause some plants to form wilted bearing spikes. Although some may be able to head, because of insufficient nutrients and moisture, the number of fruited grains per spike are reduced, and the weight of grains drops. Zhengjizng Prefecture's Agricultural Science Institute measured the wheat varieties "ning mai No 3" and "zheng 7630" from 1979 to 1981: When the diseased spots occur on the leaf sheath of the reverse third leaf, the thousand-grain weight drops 2.8 to 3.2 grams. When the diseased spots occur on the leaf sheath of the reverse second leaf, the thousand-grain weight drops 4.1 to 5.4 grams. Just this one item alone causes a loss of 11 percent to 13 percent in yield.

Different varieties of wheat show notably different resistance to Pellicularia gramineum Ikata et Matsumura. Zhengjiang Prefecture's Agricultural Science Institute tested the disease resistance of 424 wheat varieties and strains by artificial inoculation in 1981 on the basis of evaluations made during the 2 previous years. Among them, the varieties "naing mai No 3", "ning 7317", "9-10-8-3", "zheng 7630", "qun zong 42", "su mai No 3", "si mai 117", "Taishan No 1", and "Anhui 11" suffered more seriously from the disease. The percentage of diseased plants reached 16 percent to 55 percent.

To better develop the potential of increased yields of presently available superior varieties of wheat, sufficient attention must be paid to the prevention and control of Pellicularia gramineum Ikata et Matsumura, especially in regions along the banks of the Changjiang and in southern Jiangsu where there is a lot of rain and where the temperatures are high. These conditions frequently cause damage due to dampness or overcast. Prevention should be the main effort in the prevention and control of Pellicularia gramineum Ikata et Matsumura, and prevention and control should be comprehensive. First, all ways must be used to increase the application of organic fertilizers. Attention must be paid to timely sowing. Furrows should be dug to reduce dampness, and weeds should be removed. In prevention and control by chemicals, emphasis should be placed on wheat fields of the early crop of susceptible varieties. An effective farm chemical is the jing gang [0064 1511] mycin. The first application of the chemical should be made during the period when the number of diseased plants is visibly increasing, generally during the first and middle 10 days of March. In fields where the disease has occurred early or is especially serious, the chemical should be applied appropriately earlier. Another application can be made 15 to 20 days later. For each application, 1 percent of jing gang mycin of 1 to 1.5 shi jin mixed with 10 shi dan of water per mu can be sprayed manually or by machine. If the chemical is mixed with 120 to 150 shi jin of water as a mist, the chemical solution should be strictly sprayed at the base of the wheat plants to enable the chemical solution to come into widespread contact with the germs. The effectiveness of prevention generally can reach about 70 percent. In regions where the disease occurs frequently or where the disease is serious, during autumn sowing, 1 percent jing gang mycin of 1.5 shi jin per mu can be used on a trial basis to cover the seeds to reduce rotting of buds. The rate of germination can reach above 91 percent, higher than the control by 10 percent to over 28 percent.

BRIEFS

AGRICULTURAL MEETING--On 10-14 July, the provincial agricultural department held a meeting of responsible persons of agricultural bureaus of the prefectures and Nanjing city to work out plans on autumn farming following the good summer harvest. This year's good wheat and rape harvest is largely attributable to expanded acreage. This was done at the expense of winter green manure acreage and rational crop rotation. Also, the broadcast sowing and continuous growing of wheat have resulted in widespread growth of weeds in 5 to 6 million mu of land, causing a loss of nearly 100 million jin of grain. The meeting called for proper planning on autumn planting, rational crop rotation and other remedial measures. [Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 17 Jul 82 OW]

GRAIN PRODUCTION--By the end of June, the state had purchased more than 3.6 billion jin of summer grain in Jiangsu Province, 12.5 percent above the state plan, or 1.1 billion jin more than in the same 1981 period. The amount of rapeseed purchased was 660 million jin, 20 percent above the state plan, or 220 percent more than in the same 1981 period. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 3 Jul 82 OW]

XUZHOU PREFECTURE STORM DAMAGE--Xuzhou Prefecture, Jiangsu, has drained 4 million mu and repaired 680,000 mu of corn and cotton fields damaged by recent heavy rains, wind and hail. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 11 Aug 82 OW]

RURAL HOUSEHOLD INCOME--According to a survey conducted by the Jiangsu Provincial Statistical Bureau, of 1,000 rural households at 71 points in 22 counties, commune members' income in the first half of 1982 increased 38 percent over the same period last year, with per capita income reaching 109.3 yuan, an all-time-high. [Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 12 Aug 82 OW]

YANCHENG PREFECTURE AGRICULTURAL PRODUCTION--Jiangsu's Yancheng Prefecture increased its annual total grain output from 4.5 billion jin in 1978 to 5.3 billion jin in 1981, cotton from 2.59 million dan in 1978 to 3.94 million dan in 1981. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 12 Aug 82 OW]

HUAIBEI REGION RAINSTORM--From the evening of 21 July to the morning of 22 July, Huaibei Region which includes Jiangsu, Anhui and Henan Provinces, had a torrential rainstorm over a large area. 25 cities and counties, 8 of which are in Jiangsu Province, had over 100 mm of torrential rain within 12 hours. Zhumadian in Henan Province had up to 307 mm, Xiao County of Anhui Province had up to 361 mm and Xuzhou Municipality, also of Anhui, had up to 234 mm of rain. Since the rainstorm, the middle and upper reaches of Huai He beyond Lake Hongze have produced a floodwater capacity over 12 billion cubic meters. Bangfu Dam had, by 27 July, a flood-peak flow capacity of 8,000 cubic meters per second. On 29 July, Lake Hongze had a flow capacity of about 9,700 cubic meters. Peicang Prefecture near Yi He (in Anhui) and Shu He (in Jiangsu) had rainfall of 100 mm. Lake Luoma had 600 million cubic meters of water. The water level of the Lixia He area after this rainstorm was expected to rise to 1.6 meters. The areas affected by the rainstorm have mobilized in all-out way to combat flooding and waterlogging. [Excerpts] [Nanjing XINHUA RIBAO in Chinese 23 Jul 82 p 1]

BACTERIAL INSECTICIDES--Nanjing, 17 Jul (XINHUA)--A method of vegetable pest control by bacteria is being applied to 1,130 hectares of vegetables, about one-fourth of the vegetable gardens in the suburbs of Nanjing, according to the city's vegetable research department. The bacterial insecticides used in Nanjing belong to the bacillus thuringiensis family and have evidenced little pollution or side effects thus far. They are more effective in killing such farm pests as cabbage worms and moths than other pesticides. One kilogram of the bacterial insecticide, which can be used on 0.5 hectares to 0.6 hectares, costs only 2 to 3 yuan. The expenditure of bacterial insecticides per hectare is 50 percent less than the farm chemicals. With the bacterial insecticides, the vegetables appear to grow better than those applied with farm chemicals, and do well on the market. The study and experiments on the bacterial insecticudes began in 1977. [Text] [OW181818 Beijing XINHUA in English 1219 GMT 17 Jul 82 OW]

PEASANTS' PURCHASING POWER INCREASES

SK120747 Changchun Jilin Provincial Service in Mandarin 1100 GMT 11 Aug 82

[Text] Since the 3d Plenum of the 11th Party Central Committee, our province has made a great development in agricultural and sideline production, enabling the rural economy to enliven and the peasants to increase their income while continuously improving their lives and their purchasing power, thanks to the further implementation of the party's rural economic policies.

According to statistics, the peasants' purchasing power for commodities in the province in 1981 was 3.1 billion yuan, an increase of 55.8 percent over the 1978 figure and an average increase rate of 15.9 percent a year, which was higher than the 14.8 percent annual increase of urban people's purchasing power.

The commodities that the peasants bought showed a great change because of increased improvement in their standard of living. In the past, peasants put the materials of daily life before the materials of agricultural production in their purchases. Food, clothing and daily necessities of dependable quality were the most popular goods. At present they give priority to purchasing the means of agricultural production and buy consumer goods in a choosy way with an emphasis on improving living conditions.

In 1981, the supply volume of agricultural production materials for the supply and marketing cooperatives throughout the province showed an increase of 52.3 percent over that of 1978. The increase in agricultural production means was three times the increase of consumer goods. In 1981, the sales of chemical fertilizers reached 1,680,000 jin, an increase of 96.7 percent over that of 1978. The sales of pesticide, farm plastic film and medium- and small-sized farm tools increased by a large margin.

The retail sales volume of consumer goods increased 16.7 percent over that of 1978. The sales of 48 major industrial products showed comparable increases; particularly such durable consumer goods as bicycles, radios, sewing machines, clocks and watches showed great increases in the past three years. The sales of those five durable consumer goods in the period of 1979 to June 1982 witnessed increases like those of the 1974-1978 period. The continuous increase of the supply of commodities to rural areas alleviated the short supply of durable consumer goods.

CSO: 4007/537

BRIEFS

GRAIN PURCHASE--Peasants in Tumd Right Banner, Nei Monggol Autonomous Region, have actively sold wheat to the state. By 3 August the banner had set aside for storage 810,000 jin of summer grain, doubling the corresponding 1981 figure. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 7 Aug 82 SK]

GOOD CROP EXPECTED--Ju Ud League, in Nei Monggol, is expecting a good harvest. Barring extraordinarily serious natural disasters in the future, there will certainly be an exceptionally good harvest. The league cultivated 62,353,000 mu of crops this year, of which 10,833,000 mu are grains and soybeans and 258,000 mu are oil-bearing crops. [SK051222 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 31 Jul 82 SK]

LIVESTOCK PRODUCTION--Despite successive years of drought, in Ju League, Nei Monggol Autonomous Region, is having good results with livestock production. The number of livestock in the league exceeds 6 million, 74,000 head more than in 1964, a year that boasted the largest number of livestock. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 3 Aug 82 SK]

LIVESTOCK OUTPUT--Hulun Buir League, Nei Monggol Autonomous Region, has made great progress in raising milk cows. The league has over 38,000 head of milk cows. There are over 15,000 households in the league which have engaged in raising milk cows. In the first half of 1982, the league registered a 1.8-fold increase in milk procurement over previous records. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 5 Aug 82 SK]

ULANQAB LEAGUE LIVESTOCK OUTPUT--Ulanqab League, Nei Monggol Autonomous Region has reaped a bumper harvest in animal husbandry this year. According to statistics, the league has over 6.66 million head of animals, a 24.2 percent and 150,000 head increase over the figure of the corresponding 1981 period. Meanwhile, the league has built over 100,000 mu of man-made pastures and has registered over 1 billion jin increase of fodder grass over the 1981 figure, which may be consumed by 185,000 animals. According to statistics compiled at the end of the fiscal year, the league registered a 30,000 head increase of female animals and a 207,600 head increase of young animals over the figures of the corresponding 1981 period. [SK060552 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 5 Aug 82 SK]

RAINFALL REPORT--Some areas in Nei Monggol Autonomous Region have had rain in the past few days. Precipitation ranged from 30 to 100 mm in Ih Ju and Ulanqab leagues and Hoohot and Baotou municipalities, according to statistics released on 3 August. Otog and Hanggin banners have had 56 and 30 mm of precipitation respectively. The rains are conducive to the growth of field crops and to easing the drought in the western part of Ju Ju League. NEW EMPHASIS GIVEN HOUSEHOLD RAISING OF LIVESTOCK, POULTRY

Jinan DAZHONG RIBAO in Chinese 26 Jun 82 p 1

[Article: "Effective Way To Develop Livestock Industry. Taian Prefecture's Experiences in Livestock Production of Using the 'Four Households,' All Rising Together"]

[Text] Taian Prefecture has summarized the lessons of past experience to adopt a system of "four households" all rising together to hasten growth of the livestock industry. This is a new road they have pioneered through practice for fairly rapid growth and fairly high economic benefits.

In this prefecture's development of the livestock industry, by the "four households" is meant specialized households, key households, combinations of households, and ordinary households. Specialized households are households that have contracted care of collectively owned livestock. In addition, they are households that use their own funds, equipment, and skills, and with the support of the collective, have net earnings of more than 1,000 yuan from the livestock industry. Most of the workforces in these households are engaged in livestock industry production; most do not contract to farm land; and some of them farm only fields to produce their grain rations and livestock fodder in a gradual movement toward specialized farming. Key households both contract the farming of land and the raising of livestock and poultry. The collective permits one member of the household's workforce to engage solely in livestock production. Net earnings from the livestock industry amount to more than 500 yuan. They sign economic agreements with production teams, and within households there are the beginnings of a specialized division of labor. Combinations of households means peasant households that have a fairly large surplus of work days, but that themselves have difficulties in developing household livestock raising enterprises and thus receive support from the collective, the commune members turning over to the collective funds, and manure as stipulated, with workpoints being recorded and participation in distributions permitted, the households themselves deciding the kinds of livestock they will raise. Sometimes the livestock are purchased by production teams and raised by households, contracting being done with the collective for a small amount of livestock or poultry, such as contracting for one or two head of cattle or several hogs. Ordinary households means common peasants who develop livestock raising industries with the help of household workforces, using their own fodder and customary methods. No matter what type of household, all institute centralized management, and all receive support from the collective with some funds (or young livestock), fodder (or fodder producing land), with commune members turning over funds and manure to the collective, having workpoints recorded, and participating in distributions. This method not only makes the most of the superiority of the collective economy, but also arouses the initiative of individual commune members. It both insures growth of key households and maintains a mass aspect. This is a new path for gradual specialization and development of commodity production in the livestock industry following general institution of production responsibility systems. Now the number of specialized households, key households, and combinations of households in Taian Prefecture has grown to more than 400,000, accounting for one-third the total number of peasant households in the prefecture as a whole. Last year the prefecture's livestock industry reached an all-time high, with gross earnings amounting to 167 million yuan, which was 15 percent of gross agricultural earnings.

Though not much time has passed since adoption of the "four households" rising together system for growth of the livestock industry in Taian Prefecture, there have been evident advantages: First is an all around growth of the livestock industry, the six major livestock animals proliferating. The "four households" all rising together method has focused development of the livestock industry on the myriad of peasant households, bringing together through economic support the collective and commune member families, both working in harness together, each household developing and being able to raise whatever animals it likes, or raising whatever is needed, for an initial change in the imbalance within the livestock industry. Raising of large livestock has rapidly climbed again; steady growth has taken place in hog raising, and the raising of sheep and goats, rabbits, and poultry has seen all around development. A survey done in Loyao Production Brigade, Feicheng County shows that this brigade developed more than 300 specialized households, key households, and combinations of households last year, and that the number of large livestock increased from 105 head to 490 head; the number of sheep and goats rose from 37 to 802; the number of rabbits increased from 87 to 3,200; the number of poultry went from 3,000 to 12,600; and the number of live hogs being fed rose by 600 head. Earnings from the livestock industry in the brigade amounted to 30.2 percent of average distributions. Second, is gradual movement toward specialization and development of commodity production. Last year, of the prefecture's more than 100,000 specialized households, key households (accounting for 8 percent of the total number of peasant households in the prefecture) produced 80.2 million yuan net earnings from the livestock industry. This amounted to almost one-half the total earnings from the livestock industry in the prefecture as a whole. In Fengtai Brigade, 150 specialized households and key households last year alone provided the country with 200,000 jin of various kinds of meat, an average per household contribution of 1 ton of meat. The commodity rate rose, and costs noticeably declined. A survey of 100 production teams in Taian and Laiwu counties showed more than 25 percent less labor being used than last year by specialized households raising animals, and a 30 percent saving in forage grass, plus about a 25 percent saving in feed. Third is use of traditional livestock raising skills and promotion of new livestock raising techniques. Specialized households and key households have both made the most of commune member proficiency in a particular line, and have become leading households in the promotion of advanced feeding techniques. At the present time, an unprecedented enthusiasm for "science" has occurred among the prefecture's households engaged in the raising of livestock. Everywhere the peasants are seeking fine breeds, inquiring about feed formulas, and asking advice on ways of preventing and treating diseases. They are striving to raise fine breed livestock and poultry, striving to use mixed feeds, and striving to use advanced, scientific feeding techniques. Formerly the entire prefecture annually bred only 200,000 fine breed chickens, but in a single quarter of this year breeding was expanded to more than 1.8 million. Fourth is use of local funds to tap production potential. With development of the livestock industry, various sources of forage grass and livestock feed and family compounds have been put to full use, and members of commune households are able to play a role in the livestock raising industry. Commune member Yang Ruxiang [2799 1172 4382] of Shengzhuang Commune in Taian City had a crippled son who formerly had nothing to do at home for many years. After his family became a specialized household and labor was equitably divided among family members, he became the mainstay in livestock raising. Last year alone the family raised 13 head of hogs, plus two sows, five oxen, and also contracted the raising of 13 hogs for the production team. Thanks to the painstaking care and scientific feeding done by the family as a whole, net income amounted to more than 3,200 yuan. Last year more than 100,000 specialized households and key households in the prefecture had average per household earnings of 764 yuan, and 18,000 specialized households had net earnings of more than 1,000 yuan.

In adopting the system of "four households" all rising at the same time for development of the livestock industry, Taian Prefecture made sure to master four problems as follows: 1) Adaptation of general methods to specific situations and proceeding in accordance with capabilities. In the development of various forms of livestock feeding households, communes and brigades made sure on the basis of individual economic strength, the workforce situation, natural resources, and the livestock raising habits of the masses, to develop whatever kind of household that was suitable, and to raise the kinds of livesotck that could be raised with no "arbitrary uniformity." 2) Diligent implementation of policies and supporting all types of households in developing household livestock feeding industries, thereby linking the collective and commune member household so that the myriad of peasant households and the collective formed a totality. Prefecture support to commune members took four main forms as follows: One was collective support with some funds and help in the purchase of livestock (or poultry) to those households who increased the raising of livestock and poultry above and beyond the already established household livestock raising industry, repayment being made after the households realized earnings. Second was help in solving problems in getting forage grass and livestock feed. In some cases those raising a large number of livestock or poultry were assigned land for the raising of livestock feed; in other cases, forage grass or livestock feed was apportioned on the basis of distribution prices; and in still other cases, help was given with the processing and mixing of feeds. Third was help in building of livestock pens and poultry coops. In some cases the collective provided the labor and materials; in some cases consturction was done centrally, and in some cases help was given in the form of some materials or workpoints. Fourth was the use of bonuses, bonus workpoints being awarded on the basis of the number of livestock raised in some cases. In other cases a system was used whereby little cash was surrendered to higher authority and high distributions were made, meaning surrender of money to the production team at a rate of from

10 to 20 percent below the production team individual work value, but distributions being made on the basis of total work value. 3) Establishment and perfection of an all around service system. To meet needs of "four households" rising at once, the prefecture set to work to establish several service systems. One was a livestock and poultry fine species breeding system. In addition to the fine breed farms established by the prefecture and counties, 900 fine breed livestock and poultry breeding households and 340 stud livestock households were developed. A second was a veterinary medicine service system. In addition to operating county and commune veterinary medicine stations, all production brigades trained one or more veterinary personnel, and promoted contracting of livestock and poultry epidemic prevention and livestock raising care techniques. Third was a livestock feed service system. Some communes and counties began to construct livestock feed processing plants, and most production brigades set up livestock feed processing plants. Fengtai Production Brigade in Taian City established a livestock feed production and supply cooperative to produce balanced livestock feeds for livestock raising households. Loyao Production Brigade in Feicheng County established a livestock feed processing plant with a daily output of 10,000 jin. Fourth was a production and marketing service system. The prefecture established an integrated livestock, industrial, and commerical company, and six different communes established economic diversification service companies or trade warehouses. Culai Commune warehouse in Taian City signed an agreement with Shanghai for the raising of geese, last year supplying Shanghai with 350 tons of goose. This year they signed another agreement for 1,200 tons. 4) Good ideological work to assure the handling of matters in accordance with agreements. In the institution of "four households" all rising together, in addition to continuing to be guided by state plan and under the centralized direction of production teams, it is also necessary to give attention to frequent education of the various kinds of livestock raising households in patriotism and collectivism so that while they are developing household livestock feeding, they will think of the country and the collective and consciously handle matters in accordance with agreements, first of all assuring fulfillment of state procurement plans for livestock and poultry, surpluses being sold in markets, and also turning over funds and manure to the collective as agreed, in the proper handling of the interests of the country, collectives, and individuals.

BRIEFS

AGRICULTURAL MEETING--On 16 July, the Zhejiang Provincial Party Committee and people's government held a province-wide broadcast rally on summer harvesting and planting, calling for efforts to overcome natural disasters and win victory in summer harvesting and planting. Vice Governor Wu Zhichuan presided over the meeting. Chen Zuolin, secretary of the provincial party committee and vice governor, spoke. He called for efforts to fulfill the year's grain output target of 30 billion jin. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 16 Jul 82 OW]

GRAIN PROCUREMENT--Recently the provincial food department held a meeting of prefectural and city food bureau directors to arrange early and middle-season rice procurement and storage work. Vice Governor Wu Zhichuan spoke at the meeting. He said that a good early rice harvest is in sight in the province. Thus far, more than 600 million jin of spring grain have been procured and put in storage in Zhejiang, overfulfilling the provincial spring grain procurement target by 32 percent. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 17 Jul 82 OW]

FARM, SIDELINE PRODUCTS--During the first 6 months of 1982, Zhejiang procured 17,350 million yuan worth of farm and sideline products, marking an increase of 4.5 percent compared with that in the same period in 1981. They include 5.53 million hogs, 1.42 million dan of tea and many other products. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 25 Jul 82 OW]

LAND RECLAMATION--Since 1978, Zhejiang has reclaimed over 1 million mu of cropland from tidal land, hilly areas and river banks. The reclaimed areas produce 300 to 400 million jin of grain and other agricultural produce a year. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 9 Aug 82 OW]

COMMUNE, BRIGADE PRODUCTS--During the first half of 1982, Zhejiang's commune- and brigade-run enterprises turned out 2.7 billion yuan worth of products, marking an increase of 8.9 percent over that of the same period in 1981. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 26 Jul 82 OW]

I. GENERAL INFORMATION

SCIENTIFIC USE OF PESTICIDES OUTLINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 17 Jun 82 p 4

[Article: "Scientific Use of Chemical Pesticides"]

[Text] Use of chemical pesticides is a major current technique for eliminating or reducing losses caused to farm crops by diseases, insect pests, and weeds. However, if used improperly the goal of prevention and control will not be attained or damaging side-effects may be produced. Therefore, we have to understand the properties and methods of use of various kinds of pesticides as well as understand diseases, insect pests and weeds if chemical pesticides are to be used scientifically.

1. Understanding pesticide properties so as to suit the remedy to the problem. In addition to understanding the chemical properties of various pesticides (such as volatility, solubility, hygroscopicity, and toxicity), it is also necessary to understand their methods of use (whether they are stomach poisons, contact insecticides, systemic insecticides, or fumigants). One must also understand the objects to be controlled (whether insecticides, bactericides, acaricides, or herbicides are to be used), and how to use them. Benzene hexachloride, for instance, is a broad sprectrum insecticide for the elimination of many kinds of harmful insects; however, it causes very little damage to Prodenia litura. For use, 3 jin of a six percent powder is mixed with 30 to 50 jin of fine soil per mu, and scattered evenly on the ground. Alternatively between 1 and 1.5 jin may be added to about 800 jin of water and used to water the ground to prevent damage from paddy borers during the seedling stage and the panicle formation stage of rice. Before the tassel has formed on corn, a six percent miscible powder in a 600 volume solution may be used to water the central leaves to prevent and control corn borers with good effect.

2. Accurate diagnosis with prompt use of the right pesticide for the disease, insect pest, or weed situation. Diseases, insect pests, and weeds vary in their sensitivity to pesticides at different stages. For example insect ova and pupae are extremely resistant, but young insects have extremely weak resistance to insecticides from the time they are first hatched until they are 3 days old. Pathogenic bacteria are strongly resistant to pesticides when they are spores, but following germination, their resistance greatly weakens. Weed resistance to pesticides is weakest between the time of sprouting and the three leaf stage. Therefore, in the prevention and control

of diseases, insect pests, and weeds, pesticides should be applied when their resistance to them is weakest to eradicate them early before they can cause damage.

Insect mouths differ and react differently to pesticides. Chewing insects are very susceptible to stomach poison or contact insecticides. Sucking insects are very susceptible to systemic or contact insecticides. Consequently, only through accurate diagnosis and selection of the pesticide that does the job can pesticides eradicate insects.

3. Strength and volume of pesticides must be right. Arbitrary increase in pesticide strength or increases in the number of times applied are the main reasons for pesticide poisoning of crops, residual toxicity, and accidental poisoning of humans and livestock. Therefore, in using pesticides, one must determine the proper strength and volume of pesticides to be used depending on environmental conditions at the time, disease and insect pesticide resistance, the growth stage of crops, and the properties of the pesticide being used.

4. Pesticide application methods commensurate with different disease, insect pest, weed, pesticide, and climatic conditions. For example, prevention and control of harmful subterranean insects generally requires use of toxic soil, toxic bait, and treatment of the soil. Prevention and control in warehouses or other places that can be readily closed tightly entails use of fumigation methods. For pathogenic bacteria in seeds, usually a pesticide is either mixed with the seeds or seeds are soaked in it. In the prevention and control of yellow rice borers, toxic soil may be sprinkled on the ground, while prevention of rice blast requires spraying. During times of high temperatures and drought, pesticide concentrations should be reduced, and in overcast periods or when humidity is high, concentrations may be properly increased. When fairly windy, the spray head should be slightly depressed for spraying, and when there is a lot of morning dew, spraying should not be done.

5. Attention to safety of humans and livestock and prevention of pesticide damage to crops. In the case of parathion, for example, application should be made no less than 30 days before harvest; benzene hexachloride may not be used on melons; 2,4-D may not be used on dicotyledonous plants, and fenitrothion damages vegetables in the mustard family and should not be used on them. Chloropicrin should not be used to fumigate already processed grain and crop seeds. One must make certain to read labels carefully before using pesticides, and not use pesticides of poor quality. New pesticides should first be tested on a small area before use.

BRIEFS

NATIONAL POLLUTION CONFERENCE--The Science and Technology Bureau of the Ministry of Commerce recently held a national conference on research work in preventing pollution of food grain and oil in Nanning. According to research theses, our country has done a good job of studying pollution of food grain and oil. Since the state scientific and technology commission called for attaching importance to preventing pollution of food grain and oil in 1976, the Ministry of Commerce has launched many investigations and scientific examinations and has a basic understanding of the pollution situation in our country. The regional research center for preventing pollution of food grain and oil has inspected 18 types of grains and oil and taken 1,900 samples, and some effective measures were formulated. PREPARATIONS AGAINST POSSIBLE FLOODING URGED

Shijiazhuang HEBEI RIBAO in Chinese 4 Jun 82 p 1

[Article: "Provincial Government Issues Notice on Doing a Good Job of Flood Prevention Work This Year. Forecasts Call for Overly Large Amounts of Rainfall in Most Prefectures of Province Between June and August This Year"]

[Text] The Provincial People's Government has issued a notice requiring all jurisdictions to do a good job of flood prevention work this year.

The notice said that forecasts call for between 10 and 30 percent more precipitation in most prefectures of the province between June and August this year, and varying degrees of flooding and waterlogging will take place in eastern prefectures. During this year's high water season, for most of the rivers in the province this will be a moderately high year; however, fairly heavy flooding of some streams may occur. Possibility of flooding of medium and small size streams in the eastern and southeastern parts of the province is greater. It is particularly noteworthy that eastern prefectures, particularly the Sanjiang Plain, last year had a serious flood disaster and quantity of rainfall this spring was again fairly great. Further occurrence of fairly heavy precipitation will mean a continuation and intensification of the waterlogging situation. Consequently, all jurisdictions are required to do the following: 1. A good job of mental mobilization to prevent floods and eliminate waterlogging. Conscientious summarization and absorption of the lessons of last year's experiences in the struggle to prevent floods and combat disaster; education of cadres and masses in establishing a mentality of "primary emphasis on prevention to prevent recurrence of rescues," with good mental preparations being made to prevent large-scale flooding and to combat great disaster, seizing the initiative in the prevention of flooding and the elimination of water logging. 2. Careful safety inspections for flood prevention, and hastening of the pace of project maintenance and repair. All administrative offices, and municipality and county people's governments should thoroughly inspect the present condition of projects that impact over a wide area and about which safety questions are great, promptly solving problems that are brought to light. 3. Resolutely clearing obstacles that block the flow of water through watercourses to assure the capacity of streams to carry away flood waters. All municipality and county peoples governments must hew to the principles of "clearing of obstacles by those who created them." 4. Good preparations in flood situation monitoring and reporting, forecasting, communications and liaison, and materials. All levels of flood prevention, meteorology, and hydrology departments are to promptly and accurately understand and analyze the flood situation and the trend of its development, and issue timely reports. All jurisdictions are to ready materials early for flood prevention. 5. Concern for the situation as a whole, unity, and cooperation. Flood prevention work involves all departments and all units. During the flood season, and particularly when floods occur, all departments and units are to be concerned for the situation as a whole, unite, cooperate, submit to centralized direction, and diligently fulfill their flood prevention and rescue tasks.

SUMMER HARVESTING, PLANTING, FIELD CARE OCCUPY PREFECTURE

Shijiazhuang HEBEI RIBAO in Chinese 5 Jun 82 p 1

[Article: "Handan Prefecture Urgently Mobilizes For the 'Three Summer Jobs.' Focuses On High Temperatures and Hot Dry Winds, Which Have Created Seriously Disadvantageous Conditions For Production"]

[Text] In view of the seriously disadvantageous conditions for agricultural production currently caused by the onslaught of recent high temperatures and hot dry winds, the Handan Prefecture CCP Committee and government administrative offices have made urgent preparations for the "three summer jobs" [harvesting, planting, and field management]. They have required that all levels of leadership throughout the prefecture rapidly act to fully arouse the masses for triumph over adversity, and seize the opportunity for combat to fight a victorious production war of the "three summer jobs."

The Prefecture CCP Committee and government administrative offices have required all counties to centralize planning of the summer harvest as quickly as possible, to arrange for threshing grounds, and to make satisfactory arrangements for the use of machinery for harvesting, hauling, and threshing. They are to resolutely establish a mentality of struggle against drought, and to fulfill the high standards their more than 2.5 million mu corn sowing task. They should seize the opportunity for combat, use every minute and every second, and hasten the planting of corn in furrows between the wheat, and the dibbling of seeds to combat drought. When planting in furrows simply cannot be done, it should be done quickly after harvesting of the wheat. In western mountain regions where water is in particularly short supply, preparations should be made to open furrows, dig holes, and dibble the seeds. In addition, care of the spring sown cotton crop should be of majore concern. There should be prompt inspection and replacement of missing seedlings, cultivation, watering, and control of insects to assure full stands of sturdy seedlings. During the summer harvest season, if care of the cotton suffers for lack of full planning, responsibility will be fixed level by level.

The Prefecture CCP Committee and government administrative offices required all counties, communes, and production brigades in the prefecture to treat the "three summer jobs" as an overriding central task in rural villages. During the period of the "three summer jobs," the Prefecture CCP Committee and government administrative offices will resolutely reduce the number of meetings or hold no meetings at all; they will particularly not hold large conferences. The Prefecture CCP Committee and government administrative office principal leaders, and all persons in charge in various departments of prefecture organizations are to go into the frontlines to direct combat. Except for those needed for duty, all personnel in various departments of prefecture organizations are to go to counties for a period of work. Party, government, trade union, youth, women, and cultural and educational department leadership cadres are to lead groups of people to go to counties to help do the "three summer jobs." Aside from those needed for duty, all personnel in organizations under direct control of counties (or districts) are to work in communes and brigades. All industrial and commercial units are to formulate plans for vigorous support of the "three summer jobs," and all work must make way for the "three summer jobs."

CALL FOR ALL-TIME HIGH FARM OUTPUT PUBLICIZED

Shijiazhuang HEBEI RIBAO in Chinese 3 Jun 82 p 1

[Article: "Unprecedented Increase This Year in Turnout of Work Forces, Draft Animals, and Farm Implements. Party Policies Used To Stir Enthusiasm of Masses. Prefecture CCP Committee Calls For War on 'Two Disasters' Following Completion of Spring Sowing For High Yields and To Win a Bumper Harvest To Create an All-Time High in Agricultural Production"]

[Text] As of the end of May, spring sowing had been substantially completed in Zhangjiakou Prefecture. The Prefecture CCP Committee and government administrative offices called on people throughout the prefecture to advance on the crest of victory to take effective action in a "war on the two disasters to bring about high yields and win a bumper harvest," in an effort to surpass all-time highs for grain and edible oil production and average per capita economic income.

Zhangjiakou Prefecture has had consecutive years of drought. Last winter and this spring the broad masses of cadres took various actions to combat drought and assure spring sowing. As of 25 May, except for short season crops such as naked oats and broomcorn millet, spring sowing had been virtually completed throughout the prefecture. Spring sowing this year was characterized in the following ways: First was sowing on time. The sowing of all staple crops was finished ahead of schedule, the sowing season lasting 10 to 15 days, which was shorter than previous years. Second was good quality of sowing. The soil was painstakingly prepared; base fertilizer sufficed; planting was done scientifically; and in the sown fields there was no sight of stubble, clods of soil, or of hard or grassy embankments between fields. Seedling growth was even, in full stands, and strong. Third was an increase in the area planted. Embankments between fields were removed and weirs developed; something was planted in every crack; unused bits of land were planted, undeveloped and waste lands were plowed and planted, about 400,000 mu more being planted in the prefecture. Fourth was intercropping of numerous varieties. In Zhuolu County, for example, intercropping of corn and wheat was increased by 8,000 mu; intercropping of corn and potatoes was increased by 7,000 mu; and intercropping of corn with garlic and onions was increased by 20,000 mu. Some hilly areas intercropped five sets of crops, as follows: corn with soybeans, millet with red beans, potatoes with string beans, rapeseed with sunflowers, and sunflowers with black soybeans.

The broad masses of cadres and people felt that the emergence of such a fine situation in the farflung rural villages of Zhangjiakou Prefecture resulted from the carrying out of the spirit of the Hebei Work Conference that the Central Committee convened last July, and of the work conference convened by the Provincial CCP Committee in September, which aroused people's enthusiasm for socialism and their determination to do a solid job of production. All levels of leaders have changed their work styles, have immersed themselves in realities, have gone in big for investigation and study, have adhered to the principles of seeking truth from facts, the mass line, and self-determination. They have adapted general methods to specific situations, provided tailored guidance, come to grips with key matter, placed emphasis on main points, have brought their thinking and their work in line with that of the masses, and have encouraged the broad masses of commune members to combat disasters to win a bumper harvest. They have resolved flatland farming programs, gaining the support of the masses thereby. They have resolutely and forthrightly instituted agricultural production responsibility systems, closely linking the responsibilities, rights, and benefits of the peasants and arousing mass enthusiasm for production to an extremely great degree. The turnout of workforces, draft animals and farm implements for spring sowing this year was unprecedented. Wanquan County, with workforces totaling 57,000 actually turned out 70,000 people. Turnout of draft animals and implements in the four flatland counties increased by 69 percent over last year. Formerly it had been one implement for every three draft animals, but this year many places had one plow per draft animal. This assured the smooth completion of spring plowing and sowing.

Recently the Zhangjiakou Prefecture CCP Committee diligently analyzed the current fine situation and called upon people throughout the prefecture to advance on the crest of victory to prepare for a 100 day war in field care in an effort to achieve the objectives of all-time highs in grain and oil bearing crop production and average per capita income. It put forward the following specific requirements. One was to take hold of crucial matters and take effection action to triumph over the two great disasters--the choking drought and early frost--the main attack being directed against victory over the choking drought. The second was all around intensification of field care, at the same time giving serious attention to major crops, the key ones being corn, gaoliang, millet, naked oats, wheat, paddy rice, potatoes, and flax. The third was both concurrent concern for the situation as a whole and for key points in the use of leadership forces, with strengthening of leadership in key grain producing communes and brigades (one-fourth the number in the prefecture), while at the same time giving needed technical and material support so that these communes and brigades could create new highs and climb new peaks. Also necessary was attention to low yield areas where high potential existed. Fourth was establishment of a concept of large scale agriculture and large scale grain production on the basis of a program of "positively no slackening in grain output with active development of economic diversification." While giving attention to field care of grain and oil-bearing crops, all around attention had to be given to farming, forestry, animal husbandry, sideline occupations, and fisheries, and to commune and brigade enterprises, as well as to commune household sideline occupations. Fifth was the need to use currently perfected agricultural production responsibility systems to triumph over the "two disasters" as a starting point and base point for catching up with and overtaking the all-time high, and to win a bumper harvest. All problems impairing current production in need of urgent solution had to be firmly resolved. Problems that did not greatly impair current production or problems for which there were no methods of solution at hand, were first investigated and studied.

In order to achieve the goals of "exceeding all-time highs," and so that everyone in the prefecture will know and act, the wisdom and efforts of all being pooled, the Zhangjiakou Prefecture CCP Committee issued an "Advisory to People Throughout the Prefecture" to stir discussion among the people of the prefecture and counties, communes, production teams, and households to analyze the present, to look at the year as a whole, to give attention to crucial matters, to focus on main points, and to strive for a bumper harvest.

IMPORTANCE OF SELECTING, KEEPING SEED WHEAT EMPHASIZED

Shijiazhuang HEBEI RIBAO in Chinese 3 Jun 82 p 1

[Article: "All Jurisdictions Should Emphasize Doing a Good Job in Seed Wheat Selection and Retention, Comrade in Position of Responsibility in Provincial Bureau of Agriculture Emphasizes in Conversation With Correspondent"]

[Text] Recently a comrade in position of responsibility in the Provincial Bureau of Agriculture talked to the newspaper correspondent about selection and retention of wheat seed. He asked that all jurisdictions give attention to the job of selecting and keeping wheat seeds as an important matter in the current summer harvest. He specifically raised the following several points:

1. A good job of comparison and appraisal of wheat varieties. All wheat producing counties and communes are to organize leadership cadres, technical personnel and old peasants to participate in appraisal and selection groups for the purpose of making a one-time comparison and appraisal of wheat varieties. This will be used as the basis for formulating ideas on development of varieties and crop patterns for varieties in the local county and commune, and for making specific arrangements for selection and retention of seeds. New varieties that have already been appraised by appraisal committees as producing consistently high yields, and as being strongly resistant and of good quality need not be reappraised, but rather high powered reproduction should be organized for rapid popularization.

2. The importance of and knowledge about selection and retention of seed wheat should be vigorously publicized to arouse the initiative of commune members to select and keep seeds and to increase the scientificness of selection and retention of seeds by commune members. Production teams should properly provide for the organization of workforces to get rid of mongrel breeds and inferior plants in seed fields while the wheat is in the stage of waxy ripeness. They should also harvest, thresh, and store varieties separately, selecting and retaining seeds sufficient to meet needs of this fall's wheat planting plans and crop distribution requirements. Communes and brigades practicing the fixing of output quotas on a household basis should use appraisal and selection to designate specialized households for retention of seeds, and solve real problems in selection and retention of seeds. They should devote particular attention to solution of problems of preferential prices for fine varieties so that households holding seeds will be able to

show some profit. State-operated seed multiplication farms and units charged with tasks to produce stock seeds should select and retain sufficient seeds required by each seed plot in accordance with requirements for matching and pairing of the "three seed-plot. [the plots for growing the sterile, sterile-free, and restorer lines needed for producing hybrids?]

3. A good job of distribution and interchange of improved varieties. For disaster area communes and brigades that lack seeds and for communes and brigades in which hybrid varieties have seriously regressed or where crop patterns have been inequitable and a change of seeds is required, communes and counties should make concrete arrangements, linking up with communes and brigades having surplus seeds and signing agreements for the exchange of fine varieties. Counties hard hit by disasters should also persevere in a spirit of self-reliance, locally preparing fine wheat varieties. If a county is genuinely unable to take care of its own needs, this should be immediately reported and the prefecture asked to help arrange a solution. When prefectures lack resources themselves to solve the need for varieties, they should so report to the province, and the province can centrally balance interexchanges among prefectures of fine varieties.

4. A good job of fine variety farming. All levels of seed units should appoint specific people at wheat propagation bases responsible for doing a conscientious job of eliminating mongrels and inferior varieties, for separate harvesting and threshing of varieties, and for making all arrangements preparatory to purchase and storage. In order to prevent blind action that results in overstocking, communes, brigades, and peasant households must be wide-rangingly stirred to sign agreements to supply fixed amounts. Seed companies can provide suitable remuneration to commune and brigade purchasing and marketing personnel on the basis of quantities fulfilled.

5. Active launching of choice process of wheat seeds. All levels of farm departments are to carry out a one time inspection and repair of existing processing machines used for selection of choice seeds. In addition to fine varieties chosen and processed by seed companies, the advantages of choice selection and processing should be vigorously publicized so that communes, brigades, or peasant households will actively serve in the choice selection, processing, and retention of seeds.

BRIEFS

HEBEI PREFECTURE WHEAT HARVEST--Xingtai Prefecture reaped a harvest of wheat despite a drought condition for the 5th consecutive year. Although the wheat field area was some 400,000 mu less than in 1981, the total output still reached 970 million mu, about 1.5 percent more than last year's. Thirteen of the 18 municipalities and counties in the entire prefecture have increased output and 4 counties have a total output of 10 percent more than 1981's. [Excerpt] [Shijiazhuang HEBEI RIBAO in Chinese 6 Aug 82 p 2]

HEBEI HOG RAISING--Shijiazhuang Prefecture maintains a normal ratio of sows as a basic condition for developing hog raising in the province. At the end of 1981, there were more than 1.7 million head of hogs in inventory. This figure represents an increase of about 2.3 percent since 1949. During these 33 years, there have been 7 cyclical periods when inventories rose and fell. The last 2 cycles were first from 1976-1979 and second from the beginning of 1980. During the first 3 years of the 1976-1979 period, the inventory rate was down, and rose during the last year (1979). By the end of 1979, there were only 2.12 million head of hogs in inventory. Since the beginning of 1980, it fell to 1.78 million head. This reduction was mainly due to an imbalanced ratio of sows. [Excerpt] [Shijiazhuang HEBEI RIBAO in Chinese 6 Aug 82 p 2]

HEBEI SUMMER GRAIN PROCUREMENT--By 20 July, Hebei Province had accumulated and stored 1.45 billion jin of summer grain, overfulfilling its summer grain procurement quota. Of the 124 municipalities and counties in the entire province tasked with summer grain procurement, 103 have fulfilled or overfulfilled their summer grain procurement work. FIGHT AGAINST DROUGHT AND INSECT PESTS OUTLINED

Efforts in Songhuajiang Prefecture

Harbin HEILONGJIANG RIBAO in Chinese 30 Jun 82 p 1

[Text] "Resist drought and insect pests like fighting fire; bend every effort to resist both disasters." This is the demand made by the Songhuajiang Prefecture CCP Committee and government administrative offices to the broad masses of party members, cadres, and the masses throughout the prefecture. At the present time 700,000 people throughout the prefecture have been put to work on an emergency basis in the fight against drought and insect pests. They have already brought insects under control over a 7.78 million mu area, which is 88 percent of the area requiring control. Throughout the prefecture, streams have been dammed up, diversion ditches have been dug, and water raising points have been built temporarily in many places. Both newly built and existing pump wells are delivering water to irrigate 1.35 million mu in amelioration of the drought.

Since May Songhuajiang Prefecture has had little rain, high temperatures, and much wind. Throughout the prefecture the water level in major streams has drastically declined, and Lalin He, Ashi He, and Mayi He have virtually stopped flowing. Most small dammed ponds and small reservoirs have dried up. The drought stricken area presently covers an area of 12.6 million mu, which is 78 percent of the total cultivated area. This includes a 6.32 million mu area that is seriously drought stricken. In mid-May a general outbreak of adult borers occurred in the grasslands, and by 15 June they had begun to threaten some farmland. This year's insect pests are a rarity in the suddeness of their arrival, the large numbers of them, and the broad area they cover.

In the fight against drought and the eradication of insects, Songhuajiang Prefecture's method has been, first of all, to increase understanding to mobilize cadres and the masses throughout the prefecture to fight both disasters at once. As a result of propaganda and education, cadres at all levels and the masses have come to understand the threat that the grassland borers pose, and their serious attention has been aroused. The entire prefecture has substantially succeeded in action both to fight drought and to eradicate insects, has placed emphasis on protecting wetland and dryland crops by doing much scraping of the soil, turning of the soil and weeding, have fully tapped water sources for irrigation to save the crops and, where conditions permit, has seized the opportunity to irrigate and provide top dressings of fertilizer. Second, it has used a combination of indigenous and foreign methods for an assault on the insects. In addition to the pesticides and pesticide apparatus provided by the province, the prefecture has also sent people outside the province to buy more than 1,000 tons of pesticide, and more than 1,300 pieces of pesticide apparatus. Many counties and communes have also set to work with native methods, using human labor to catch insects. Some communes in Bayan County have resorted to sweeping, catching, tramping on, hoeing, and burying of insects, which has brought fine results. In addition, all jurisdictions have also given attention to scientific use of pesticides to make the most of pesticide effectiveness. Some places have also linked prevention and combat against disaster, uniting to eradicate insects, solving rather well the problem of insects moving from one place to another when "you control, but I do not."

Telephone Conference Held

Harbin HEILONGJIANG RIBAO in Chinese 30 Jun 82 p 1

[Text] On the evening of 29 June, the Provincial CCP Committee and the provincial government held a telephone conference to further mobilize people throughout the province to emergency action, and to exert all efforts to triumphing over serious drought and insect pest disasters to win a victory in the struggle against disasters.

Provincial CFP Committee Secretary and Deputy Provincial Governor Wang Luming [3769 6424 2494] noted, in the course of the conference, that the drought disaster has spread throughout the province and that in most places the dry layer of soil is more than 20 centimeters deep, the area of dead plants increasing daily. Wheat yields will be seriously reduced; as nearly 500,000 mu of wetlands cannot be irrigated. Forecasts call for no large rainfalls before 5 July and a deepening of the drought. Grassland borers have broken out over a wide area in great density, and the harm they have caused is serious, greater than that of 1980. Now they have spread to 53 counties and municipalities and to 72 farms. In heavily infested fields, soybeans were completely consumed within a period of 1 or 2 days. Monitoring reports say that since grassland borers are of different ages this year, the period of harm from young ones will be protracted. Aphid and cornborer outbreaks have also occurred in some places, one after another. In the face of this serious disaster situation, all jurisdictions are to further institute full party mobilization and arousal of all the people to persevere in winning the struggle against drought and insects to protect the crops.

(1) Strengthen confidence in resistance to disasters to win a bumper harvest. There must be further intensification of political ideological work to educate the cadres and masses to overcome a sense of hopelessness and war-weariness, feelings of passivity and pessimism, and a paralyzed psychology of trusting to luck and relying on heaven to send rain, to persevere in resistance to drought and elimination of insects so that there will be no let up in the fight against drought short of moderation of the drought situation, and no halt in insect control until harmful insects have been eradicated, losses from the disasters being reduced to the minimum.

(2) Full use of existing water conservancy projects and facilities and use of every available means to enlarge the effectiveness of irrigation. All available electric pump wells and water pumping stations must be put to use to irrigate the land and water the crops night and day without let up. Additional sources of water have to be developed and the potential of water sources tapped through full use of all kinds of watering devices to protect and rescue the crops.

(3) Do an effective job in the use of pesticides to eradicate insects and to control harm done by grassland borers. Monitoring and reporting has to be intensified and technical guidance buttressed. Early and late spraying is to be encouraged to increase results in prevention and control. Management of pesticides should be strengthened to prevent poisoning of people and livestock. Prompt surveys of aphids and cornborers should also be conducted for timely prevention and control of damage.

(4) Strenuous efforts in scraping and hoeing the soil to protect soil moisture to promote crop development.

(5) Prompt destruction of crops in aborted fields to make way for self-rescue efforts in production by communes and brigades hit by repeated disasters.

(6) Further strengthening of leadership in the struggle against disasters. Leadership comrades at all levels are to concentrate their energies and make every effort to lead the struggle against disasters to protect the crops. They are to organize all trades and industries for vigorous support to the struggle against disasters.

Persons in charge in Songhuajiang Prefecture and Hailun County briefed the conference on their experiences in combatting drought and eradicating insect pests to protect the crops.

SUMMER PLANTING COMPLETED DESPITE DROUGHT

Nanjing XINHUA RIBAO in Chinese 6 Jul 82 p 1

[Article: Xuzhou Prefecture Fights Severe Drought In Effort to Overfulfill Autumn Quota"]

[Text] Xuzhou Prefecture cadres and masses have worked tirelessly to fight severe drought and are pledged to win a bumper harvest from this year's autumn crop.

Since June, rainfall in Xuzhou Prefecture has amounted to only about one-half the amount of normal years, and both Feng and Pei counties have had only about one-fifth the amount of normal years. Throughout the prefecture the party at all levels has organized a great awareness campaign to strengthen confidence and resolve among the broad masses of cadres and people to continue to combat the severe drought and win a bumper autumn harvest. In Feng County, where the drought has endured longest and where water sources are most lacking, the County CCP Committee used the reality of the fight against drought during the first half of the year to win a bumper summer harvest as inspiration for cadres and commune members to diligently summarize experiences, redouble their efforts, fight drought to the finish, and win a bumper autumn harvest.

Since June cadres and the masses throughout the county have used every available means to tap underground water sources. While devoting strong attention to the equipping of pump wells, they have repaired and flushed more than 1,000 wells, and have sunk more than 400 new machine pump wells and more than 11,000 hand pump wells. In addition to making full use of machine pump and hand pump wells to fight drought, Tongshan County has tapped water from subsiding mines in mining zones and waste water from mines. Shidun Commune in this county sank four new pump wells and newly equipped 70 pump wells, while at the same time using water from subsided coal mines. As a result the paddy rice area, instead of being reduced, was expanded by 5,000 mu. While combating drought to rush plant and protect the crops, Pei County fielded more than 300,000 people daily to carry, lug, and haul water enough for 90,000 mu of corn, more than 50,000 mu of sweet potatoes, and 50,000 mu of cotton. Cadres and the masses in Ganyu, Donghai, Xinyi, and Pi counties in the hill and mountain region devoted great efforts to digging down into rivers, to digging ponds, and to digging large mouth wells to combat drought and protect the crops. After more than 1 month's arduous struggle, as of 5 July the prefecture had managed to plant more than 2.4 million mu of paddy, nearly 2 million mu of corn, 1.88 million mu of sweet potatoes and more than 1 million mu of soybeans for virtual fulfillment of summer planting plans. In addition, it actively engaged in preparations to prevent waterlogging and intensification of field care.

BUMPER SUMMER HARVEST REPORTED IN SUZHOU PREFECTURE

Nanjing XINHUA RIBAO in Chinese 6 Jul 82 p 1

[Article: "Suzhou Prefecture Summer Grain Yields Up by More than 400 Million Jin. Bumper Harvest of Wheat, Barley, Naked Barley, and Rape In Suburban Nanjing Counties"]

[Text] Following two consecutive years of reduced grain output, leaders at all levels in Suzhou Prefecture assiduously summarized the lessons of experience and took action to lead the broad masses of cadre and people to win an all around bumper harvest from this year's summer crop. Summer grain output totaled more than 1.9 billion jin, a more than 400 million jin increase over last year, and a 30 percent increase. This was a second all-time bumper harvest year. Rapeseed output totalled 300 million jin, up 27 percent from last year for a new all-time record. Currently Suzhou Prefecture is further arousing the masses to action to exceed quotas for the autumn harvest, concentrating energies on taking care of more than 5 million mu of paddy.

The four suburbs of Nanjing Municipality's three counties joyously harvested a bumper summer grain crop this year. Output of wheat, barley, and naked barley for the municipality as a whole totaled more than 570 million jin, a more than 30 percent increase over last year and a four percent increase over the all-time high output of 1980. Output of rapeseed totaled 66.86 million jin, a 40.2 percent increase over last year and more than the all-time high. Every one of the 77 communes in the municipality that grow mostly grain had increased outputs.

SCIENTIFIC FARMING ADVANCES REPORTED

Nanjing XINHUA RIBAO in Chinese 5 Jun 82 p 1

[Article: "Rich Fruits of Province's Agricultural Technical Promotion Work Pile Up. Promotion of a Combination of High Yield Farming Techniques and Practical Mass Experiences"]

[Text] Since the institution of various forms of agricultural responsibility systems in rural villages throughout Jiangsu Province, a craze for the study of science and the use of science has broken out among the broad masses of peasants. In order to meet this new situation, the broad masses of agricultural science and technology workers in the province have actively promoted agricultural techniques to make an active contribution to development of agricultural production.

In recent years, Jiangsu Province has bred, introduced, demonstrated and promoted a group of fine variety farm crops, taking full advantage of the small amount of investment required, the quick results, and the remarkable increases in yields of fine varieties. In the case of hybrid rice introduced, the province has used a combination of experimentation, demonstration, promotion, and training, promoting both fine varieties and fine methods at the same time for their very rapid promotion for use throughout the province. During the past 3 years, the hybrid rice growing area has stood at around 10 million mu. Last year, yields averaged more than 800 jin per mu, more than 100 jin per mu more than yields from conventional varieties for an annual yield increase of 1 billion jin of grain. A group of new varieties of conventional rice, wheat, barley and naked barley, corn, cotton, rape, potatoes, peanuts, soybeans, and green manure crops have also made their appearance, and remarkable results in increased yields have been obtained from their promotion over a fairly wide area.

Agricultural science and technology units and agricultural units at all levels have given serious attention to the promotion of a combination of high yield cultivation techniques and mass experiences in farming. Experiments conducted by Suqian County in the use of biological energy to grow seedlings, Jianhu County hybrid rice three strain coherent matching techniques, Tangqiao Commune in Shazhou County's experiments in gaining high yields from "five struggles" with late crop wheat, Donghai County's farming experiences for bumper peanut yields, Taixing County's experiences in high yields from intercropping of corn, and the experiences of Jintan County in the use of underground ditches in wheatfields to prevent water stagnation have all been joint developments of skillful rural craftsmen and technicians, which after promotion for use have brought remarkable economic benefits.

All jurisdictions have also attached extreme importance to the promotion of farming techniques to combat disasters for consistent yields and increased yields. Water stagnation damage to wheat, barley and naked barley is one of the main reasons for the neither high nor consistent yields of wheat, barley, and naked barley in Jiangsu Province. Following many years of practice on the part of the masses and scientific and technical personnel, experience has been distilled that says, "for any given wheatfield, water should be capable of being drained from both ends through a combination of three kinds of ditches, the four sides being free and clear, with a combination of open and underground ditches so that water can pass both inside and outside." This has effectively brought under control the threat of the "three waters," and has been promoted over an area of more than 20 million mu throughout the province, thereby increasing yields of wheat, barley, and naked barley by 1.6 billion jin. In order to guard against low temperatures in early spring and frost freezes in autumn so that the cotton will form numerous bolls early, of fine quality and high yields, the province has promoted wide area use of the new technique of using plastic mulch to cover nutrient pots growing seedlings for transplanting. Last year this technique was promoted over an area of more than 5 million mu, and this year it has been expanded to more than 6 million mu. Such transplanting of cotton has increased ginned cotton yields by about 25 jin per mu, as compared with the direct sowing of cotton, for an earnings increase of more than 30 yuan per mu.

Pilot experiments that the Provincial Science Commission and the Agricultural Commission took the lead in organizing in the growing of wheat, barley, naked barley, paddy rice, and cotton on 100 mu continuous tract bumper yield fields have closely dovetailed scientific research with promotion, not only making pilot project site high yields even higher and turning low yields into high yields, but also effectively promoting balanced yield increases over wide areas, which has been heartily welcomed by the masses.

Results have also been heartening in the promotion of soil improvement through control of alkalinity through technical experiments in the rational use of chemical fertilizer and increased use of organic fertilizer. In Xuzhou and Huaiyin prefectures, through the promotion of water conservancy construction, large scale efforts in converting drylands to wetlands, the growing of green manure, and such all around control measures, 70 percent of a more than 6 million mu alkaline-saline land area has been brought under varying degrees of control. As a result of control efforts, per unit yields from mottled alkaline land in Lianshui County have been increased from the former 200 to 300 jin per mu to between 600 and 700 jin per mu. The province has also energetically popularized deep fertilization with nitrogenous fertilizer, concentrated fertilization with phosphate, follow-up leaf fertilization, and such economic fertilization techniques.

CONCERTED ACTION AGAINST CONTINUING DROUGHT URGED

Jinan DAZHONG RIBAO in Chinese 14 July 82 p 1

[Article by Commentator: "Unified Mental Perception For Strengthened Confidence in Resistance to Disasters--First Talk on Persevering in Combat Against Disasters So That the Autumn Will Compensate the Summer Harvest Shortfall To Win a Bumper Harvest For the Year As a Whole"]

[Text] During the previous period of time, all levels of the party organizations and the broad masses of cadres and people throughout the province made combat against drought the overriding central task in rural areas. With a dauntless spirit of making every moment count, they launched a struggle against drought to win very great achievements. However, the drought situation continues very serious, and the work of autumn sowing and field care has just begun. A more arduous and more strenuous struggle against drought to win a bumper harvest lies ahead. As a result of the protracted drought, in some of our cadres and masses a psychology of trusting to luck has arisen with fears of hardships and trusting the heavens to send rain. This has brought in its wake mental obstacles to continued combat against disasters. Therefore, we must unify perceptions and resolve that we will combat drought and combat disaster to the end.

This year's drought in Shandong Province follows 3 or 4 consecutive years of serious drought. Rarely has a drought been encountered that has covered such a wide area, that has been so pervasive, that has casued so much damage, and that has been so protracted. Between January and mid-May, only 65 millimeters of rain fell in the province. During mid-May most places experienced high temperatures and hot dry winds causing crop moisture to evaporate dramatically, the soil to lose moisture severly, the wheat to suffer from heat, and the spring seedlings to wither. During the past 10 days, though some rain has fallen in many places, this has not entirely solved the drought problem. Of course, while persevering in combat against drought, it is also necessary to make preparations to prevent waterlogging. It cannot be denied that serious natural disasters pose numerous hardships for us in winning a bumper harvest. However, it is also necessary to realize at the same time that we possess many favorable factors in the fight against drought and disasters. First of all, as a result of the implementation during the past several years of the CCP Central Committee's programs and policies on rural work, particularly the promotion of various forms of production responsibility systems, the mood of the broad masses of peasants has risen. As a result of all jurisdictions having summarized, perfected and stabilized production responsibility systems, and having given attention to correct handling of the relationship between "centralized" and "contracted," the initiative of both the collective and commune members for combating drought was brought into play, and development of farmland water conservancy facilities promoted. This will play a major role in assuring future struggle against drought. Furthermore, we have many years experience in combating drought to win bumper harvests. In 1980 we fought drought for a year to win a bumper harvest. In 1981, we again struggled for a year against serious drought to win a good grain harvest and a bumper harvest of economic crops. These experiences are very useful in guiding this year's struggle against disaster. It should also be realized that no matter how serious the drought, water resources in the Huang He in Shandong Province are fairly copious and that the more than 100,000 water conservancy projects that have been built since last winter have yet to show full effectiveness. Ground water also provides an untapped potential. In addition, the province's material foundation for fighting drought and disaster is also comparatively rich and industrial forces for the support of agriculture are fairly strong. As a result of consecutive years of bumper harvests, both the collective and commune members are relatively well off. Consequently, so long as we strengthen leadership, thoroughly arouse and rely on the masses, and fully utilize and bring into play these favorable factors, winning victory in the struggle against drought and disaster is entirely possible. Any pessimistic sentiments or psychological state of inertia in the face of adversity is harmful. We must overcome and eliminate them.

Combat against drought and disaster is both a major economic task and a major political task; it is currently the most important of important tasks and the urgency of urgencies in Shandong Province. All levels of party and government organizations and all trades and industries must be concerned for this overall situation, concentrate on, and serve this overall situation in planning their work. Leadership comrades at all levels must tell party members, cadres and the masses strictly according to the facts about the drought situation, the several possibilities in this year's agricultural production, and the measures that must be taken to achieve the best possibility so that inside and outside the party, from high and low, and from left to right there will be a unified perception and unified action. All party members, cadres, and the masses must be educated to have unshakeable confidence in combating disaster, to strengthen their concept of the situation as a whole, and to do a good job of uniting and helping each other, making contributions positively and with initiative in triumphing over serious drought. We steadfastly believe that so long as the entire province from top to bottom is of one mind and is persistent, even greater natural disasters can definitely be conquered to win a good harvest this year.

SWITCH FROM RESERVOIR TO WELL IRRIGATION PLANNED

Jinan DAZHONG RIBAO in Chinese 14 Jul 82 p 1

[Article: "Rational Use of Water Resources To Promote Agricultural Development. Yantai Prefecture's Plains Communes and Brigades Gradually To Phase Out Reservoir Irrigation for Well Irrigation."]

[Text] Yantai Prefecture has summarized experiences with consecutive years of drought, and in the building of water conservancy for plains communes and brigades, it has gradually instituted a phasing out of reservoir irrigation in favor of well irrigation. Reservoirs are to be used for watering in the mountains, and wells for watering on the plains in order to make full use of water resources for promotion of agricultural production.

An overwhelming majority of the gravity flow irrigation projects that Yantai Prefecture has built over the years are located in plains areas. Because units located in irrigation zones along reservoirs, irrigation ditches, and rivers have relied on the opening of sluice gates to release water for irrigation, they have neglected development of ground water. Consequently, places (like plains) with abundant ground water have used water from water deficient places (like mountains and hills) to create a situation in which the greater the water shortage, the greater the waste of water. In order to change this state of affairs, the prefecture summarized experiences and decided to fully tap and use ground water. This means that plains area units will gradually phase out of reservoir irrigation areas, allowing reservoir water to be pumped and lifted to mountain and hill areas to solve their problems in getting water for use on farmlands, woodlands, and orchards.

Yantai Prefecture has more than 1,680 large, medium, and small size reservoirs capable of irrigating a total of more than 1.2 million mu of plains land. Under normal circumstances, figuring a 400 to 500 cubic meter per mu annual water requirement, a total of between 500 and 600 million cubic meters of water would be required. The Prefecture CCP Committee, government administrative offices and each county and municipality jointly determined that beginning now there is to be a planned sinking of wells and digging of ponds in irrigation areas located along rivers and reservoirs on plains for the development of ground water through adaptation of general methods to local situations. Annually about 150,000 mu of land is to be phased out of the reservoir irrigation system in a gradual phase out of 1.2 million mu from the plains irrigation system, the reservoir water being used to irrigate mountain and hill area farmlands, woodlands, and orchards.

In order to assure realization of this strategic measure, all counties and municipalities have begun to prospect along streams in reservoir irrigation areas under their jurisdiction and to make overall plans for projects to get water in accordance with the phase out of the irrigation area. Furthermore, units that are able or substantially able to rely on existing ground water projects to solve their water problems are to have supply of water gradually halted.

AUTUMN EFFORTS TO COMPENSATE SUMMER GRAIN SHORTFALLS URGED

Jinan DAZHONG RIBAO in Chinese 20 Jun 82 p 1

[Article by Commentator: "Tap Increased Yield Potential to Insure That Autumn Harvest Will Make Up For Summer Harvest Shortfalls. Second Talk on Unflagging Combat Against Disaster So That the Autumn Harvest Will Make Up For the Summer Shortfall for a Bumper Harvest For the Year As a Whole"]

[Text] Autumn is the big season for agricultural production in Shandong Province, with both the area planted to grain and output amounting to more than 60 percent of grain output for the year as a whole. It is also in autumn that major economic crops such as cotton and peanuts are harvested, and when 80 percent of earnings from forestry, animal husbandry, sideline occupations, fisheries, and economic diversification are realized. Therefore, how good a job is done in autumn production has a bearing on the situation as a whole. This year, in particular, when there was a shortfall in summer grain production as a result of drought, a solid job of autumn production holds major significance for fulfillment of agricultural production plans for the year as a whole, for advancing development of the national economy, and for insuring the standard of living of the people. We should fully understand this point. It is necessary both to guard against and surmount feelings of war weariness occasioned by long combat against drought, and to guard against and overcome lack of confidence and passive feelings about increased yields from the autumn harvest occasioned by a lean wheat harvest. It is also necessary to comprehensively analyze the favorable conditions and the unfavorable factors in winning a bumper autumn harvest, to build up confidence, to take more action and strive to attain an autumn harvest that will compensate for the summer harvest shortfall, to make up for shortfalls in units hit by repeated disasters from units with bumper harvests, and to make up grain shortfalls through economic diversification. Only when everyone from top to bottom is of the same mind, and the wisdom and efforts of the masses pooled can there be great hope for fulfillment of grain and agricultural income plans for the year as a whole.

In launching an autumn campaign to increase output, most important is strict attention to grain production. This year the province's grainfield area has been reduced and a shortfall in wheat production has occured as a result of drought. The conflict between supply and demand of grain is a conspicuous one. We must direct serious attention to this situation and take vigorous action to strengthen summer sowing plan guidance, doing everything possible to plant more grain crops to make sure the grainfield area is fully planted. Consistently high yielding corn and sweet potato outputs are a major part of autumn grain crops, which account for more than 85 percent of the autumn grain growing area and output. General methods have to be adapted to specific situations, every effort made to enlarge the area planted to these crops, and efforts made to insure increased yields from them. Major efforts are to be made to promote intercropping to make the most of the soil's potential. Where conditions permit, economic crop fields may be appropriately intercropped with some grain crops so as to be able to harvest a little more autumn grain. The masses are to be mobilized for a major effort in active planting of "ten besides land" [Beside streams, villages, roads, houses, etc.] so long as they do not damage water and soil conservation, and for increased planting of melons, beans, and vegetables. "Early" must be the watchword in summer sowing, seizing time, and taking the initiative. Recently rain has fallen everywhere so planting must be rushed, 1 day early being a day and 1 mu more planted being a mu. Potential for increased yields through doing a good job of field care is also very great. The growing season for autumn crops is generally relatively short and room for maneuver small. Early and painstaking care must be given and scientific care practiced, including the thinning of seedlings, hoeing, giving top dressings of fertilizer, and controlling insects. How good a job is done, and how promptly it is done bears directly on the fullness of stands of seedlings, the vigor of seedling growth, the sturdiness of seedlings, and right down to bumper harvest. Promotion of advanced experiences should be well summarized, and potential for increased yields should be fully tapped. While devoting attention to grain and economic crops, economic diversification cannot be ignored either. Active work should be done in commune and brigade household industrial sideline production, the opening of avenues, the strengthening of guidance, and efforts to increase collective and commune member earnings.

The summer and autumn season is the time during which natural disasters of various kinds are concentrated, and we must base ourselves on combat against disaster to win a bumper harvest. Today, while combating drought, it is necessary to take the initiative in guarding against other kinds of natural disasters, particularly to prepare against floods and waterlogging. Shandong Province has had several consecutive drought years, so numerous units have not given sufficiently serious attention to the prevention of floods and waterlogging. Their mentality is paralyzed, and they are unprepared. Soon the flood season will be here and when torrential rains or floods suddenly occur, they will not know what to do, serious losses resulting. We must increase vigilance on this and persevere in a program of "taking prevention as the key link, prevention being better than cure" to make full preparations. This entails the clearing of drainage ditches, getting rid of obstacles that impede the flow of flood waters, and strengthening of river dikes and reservoir dams to assure a safe flood season. Monitoring and forecasting of winds, hailstones, diseases, and insect pests should be strengthened for prompt institution of preventive measures. In case of sudden outbreaks, it will then be possible to assemble manpower and resources quickly for prevention and control to reduce disaster damage, insofar as possible, to the minimum.

In short, use of autumn to supplement the summer by winning a bumper autumn harvest will be a hard fight. Cadres at all levels must stand in the forefront of the campaign to increase output and lead the broad masses of people to do the "three summer jobs" [planting, harvesting, and field care] in production solidly, to tap potential for increased output, and struggle to win a bumper harvest in agriculture for the year as a whole.

SUMMER GRAIN PROCUREMENT PROCEDURES CONVEYED

Jinan DAZHONG RIBAO in Chinese 20 Jun 82 p 1

[Article: "Bolster Summer Grain Market Management To Assure Fulfillment of State Purchase Quotas. Provincial Industrial and Commercial Administration and Provincial Grain Department Issue Joint Notice"]

[Text] Recently the Provincial Industrial and Commercial Administration and the Provincial Grain department jointly issued "Notice on Bolstering of Summer Grain Market Management." The notice said that summer grain procurement work has now begun in Shandong Province, and in order to assure fulfillment of this year's summer grain state procurement quotas, to stabilize the market and stabilize grain prices, all jurisdictions are to assiduously carry out summer grain state procurement and market management work.

The notice required all jurisdictions to diligently apply the spirit of the provincial government's "Notice On A Good Job in this Year's Summer Grain Procurement Work." During the period of intensified state procurement of summer grain, counties should publicize the closing of summer grain markets. After the markets have been closed, no unit or individual may sell summer grain in the market. After production teams and individual commune members have fulfilled state summer grain procurement quotas, those desiring to sell grain at negotiated prices may sell it to local grain departments, and grain departments are to make purchases in accordance within negotiated price limits set by the province. Negotiated price summer grain required by state-owned businesses and collectively operated restaurants, as well as by individual food and beverage customers approved by industrial and commercial administration units, may get supplies at negotiated sale prices from grain departments subject to amounts in storage and in accordance with actual needs. Counties that have fulfilled state verified state summer grain procurement quotas are to promptly publicize the opening of markets. After markets have been opened, negotiated purchases and negotiated sales of grain and oil are to be under the centralized administration of grain departments, and no other departments or units may intervene. Unless authorized, it is not permitted to go into rural production teams and markets to buy grain or oil, much less is it permitted to profiteer from grain turnovers or make purchases for hauling over long distances.

The notice also required industrial and commercial administration units and grain departments everywhere to take the initiative for close coordination with relevant railroad transportation units for the bolstering of summer grain market management and inspection work. Any summer grain ferreted out is to be procured by grain units at list prices. Hoarding and profiteering, trafficing in grain and oil, jacking up prices, disturbing the market, speculation and profiteering, and such illegal conduct is to be resolutely struck down.

FLOOD PREVENTION WORK UNDERSCORED

Commentator Urges Serious Efforts

Jinan DAZHONG RIBAO in Chinese 19 Jun 82 p 1

[Text] It has rained continuously in Shandong Province ever since the beginning of June. In most places the drought has moderated and in some places it is completely over. Forecasts call for a considerable amount of rainfall in most prefecutres of the province during this year's flood season. Right now rainfall is concentrated in the northwestern and southwestern parts of the province, and some places will be flooded and waterlogged during mid-summer. The flood season will soon be here. Positive action with strict attention to implementation of flood prevention measures to triumph over the flood and waterlogging disasters that may occur, to protect the bumper autumn harvest and to safeguard the people's lives and property is an extremely urgent and important task facing the people of the province.

During this year's flood prevention work, simultaneous with major efforts everywhere to launch struggle against drought, definite preparations must be made ideologically, organizationally, for projects, and for materials. However, inasmuch as all levels of leadership were preoccupied with fighting the drought during the previous period, many comrades turned their attentions to fighting the drought so they do not fully understand flood prevention and have not devoted sufficient attention to preparations to prevent floods. They have not taken vigorous action, and progress on some of the projects, flood prevention materials, and organization of forces has been slow. In places along the Huang He, in particular, large scale diversion of the Huang is continuing and has raised the water table. In some places there is continued construction of production embankments in the river shallows, which obstruct water flow. Thus, should torrential rains or floods occur, it would be extremely easy for accumulated waterlogging to turn into a disaster. Right now people throughout the province are doing everything possible to create conditions for a bumper autumn harvest. Moreover, diligent work in prevention of floods to assure safe passage through the flood season is a major action for winning a bumper harvest, so that the autumn harvest can make up for the summer harvest shortfall. If vigilance is relaxed and problems arise in flood prevention, the crops that cover the land will sink into a boundless sea of water with direct consequences for development of agricultural production throughout the province and for social order.

Therefore, we must increase understanding about the importance of flood prevention work, resolutely overcome a paralyzed mentality and a psychology of trusting to luck, "preferring to believe a flood may happen rather than that it will not," firmly implant a mentality of combat against great flooding and prevention of great waterlogging, and genuinely devote strict attention to flood prevention work.

Leaders everywhere must proceed from local realities to carry out at once discussion and study of flood prevention work, organize forces for a general inspection before the advent of floods, and devote strict attention to solving existing problems. Leadership has to be strengthened and sufficient workforces made ready for an assault on the repair of hazardous projects. Prefectures along the Huang should immediately call a halt to diversion of the Huang and stop new construction or increasing the height of production embankments in the shallows of the Huang He. They should also open up entrances for water to pass through in accordance with regulations. Plains prefectures should also drain, in a planned way, water stored in brooks, and demolish large gates that intercept the flow of streams, give attention to restoring breeches in flood prevention dikes, open up ditches made of sticks, and clear away obstacles to the movement of flood waters. In the case of hazardous projects that cannot be remedied for the moment, emergency measures are to be diligently implemented for safe passage through the flood season with a tightening of defenses to assure safety. For all water conservancy projects including the Huang He, inland streams, and reservoirs, a flood prevention corps should be rapidly organized and sufficient flood prevention materials made ready to insure rescue needs. Responsibility systems are to be instituted at every level. Leaders at all levels engaged in division of labor for flood prevention work are to earnestly rely on superior authority for instruction, take urgent action, and have a firm grip on implementation of measures. During the flood season emergency period, on-site direction should be done and every effort made to assure that no problems arise during the flood season so as to win an all-around victory in the flood prevention struggle.

Flood Prevention Conference Held

Jinan DAZHONG RIBAO in Chinese 19 Jun 82 p 1

[Text] On 17 June the Provincial Drought Combat and Flood Prevention Command held a command conference that asked all jurisdictions to overcome a paralyzed mentality and come to grips with implementation of various flood prevention measures to meet head on the floods that may possibly occur.

The conference was presided over by Provincial CCP Committee Secretary and Deputy Governor Comrade Li Zhen [2621 2182]. Deputy governors Zhu Qimin [2612 1142 3046] and Zhu Zhenxing [0719 2182 5281], as well as individual deputy commanders and leading members attended the conference.

At the conference, the Provincial Water Conservancy Department, the Huang He River Affairs Bureau, and the Provincial Meteorology Bureau individually reported back on the current status of flood prevention preparations and the meteorological outlook during this year's flood season. They unanimously agreed that the several most recent rainfalls have moderated the drought in most of the province's prefectures. The flood season will soon be here, so all jurisdictions should proceed from realities and places that have had much rainfall in particular, should turn their major efforts toward flood prevention work. In places where the drought situation is not completely over, both continued efforts should be made to combat drought, and active preparations should be made to prevent floods. There should be no paralyzed mentalities or trusting to luck. Where drought exists, drought should be fought; where floods exist, there should be prevention of floods, everyone basing themselves on combat against disaster to win a bumber harvest.

The conference noted that during the previous period all jurisdictions had already done a certain amount of work of flood prevention. However, these are woefully inadequate for defense against the great floods that may occur. Cadre and mass mentalities are paralyzed; the pace of projects to get through the flood season is slow; no flood prevention corps has been put in place; and material preparations are inadequate. Were torrential rains and floods to occur suddenly, they would be caught unawares.

The conference stressed that flood prevention work bears on the overall circumstances of the national economy and on the safety of the people's lives and property. All levels of CCP committees and government must genuinely strengthen leadership of this work, overcome paralyzed mentalities, take a firm grip on implementation of measures, their thinking proceeding from the very worst possible situation while striving to achieve the very best possible situation so that they will be prepared for rain whether it rains or not, and will think in terms of large rains rather than small rains. All jurisdictions are to conduct at once a diligent and comprehensive inspection of flood prevention work, to institute level by level responsibility with individual responsibility being designated, rapidly institute a flood prevention system, rely on instructions from above in division of labor, conscientiously solve existing problems, arouse the masses for an assault on the repair of projects to get through the flood season, take firmly in hand the reclosing of breeches in flood prevention dikes, clear away obstacles to the water, organize a flood prevention corps, prepare sufficient amounts of rescue materials, and make all preparations to meet a large flood head on. By way of inspecting flood prevention preparedness, the conference stipulated the organization of four flood prevention inspection teams led by three department and bureau directors who recently arrived in the key areas of northern Shandong, southwestern Shandong, and south central Shandong to inspect, supervise, and spur along, helping all jurisdictions rapidly institute various flood prevention measures in order to triumph over the flood and waterlogging disasters that may occur and win a bumper autumn harvest in agriculture.

IMPETUS GIVEN FARMLAND WATER PROJECT RESPONSIBILITY SYSTEMS

Jinan DAZHONG RIBAO in Chinese 14 Jun 82 p 1

[Article: "Good Use of Water Conservancy Facilities To Make War Against Drought More Effective; Yanggu County Summarizes and Promotes Water Conservance Management Responsibility System"]

[Text] Yanggu County has summarized and promoted water conservancy management responsibility systems to make full use of the role of farmland water conservancy facilities and expanded their effectiveness in combating drought.

After most brigades in this county instituted responsibility systems of fixing output quotas on a household basis with households assuming full responsibility for task completion, some cadres were fearful that fields had been divided into too small plots and that farmland water conservancy facilities could no longer continue to be used to benefit. Following thoroughgoing investigation and study by the county, the experiences of representative units were summarized and promoted. After Litai Commune instituted production responsibilty systems, it also established a water conservancy facilities management responsibility system. In cases where pumping stations, bridges, culverts, and sluice gates, underground conduits, and such trunk projects cut across commune and brigade jurisdictions, persons were designated responsible for management. Wherever a trunk ditch crossed a field for which a household was responsible, responsibility for its maintenance, for leveling of the land, and for field projects was contracted by the household. In addition, depending on the situation in individual brigades, a system was adopted whereby existing water conservancy machinery was owned by the collective and its use centrally administered, brigades owning it with its management being done by teams and its use being contracted to individuals fees collected on a per mu basis. This made full use of the role of water conservancy machines. Throughout the commune, the in-operation rate of pump wells, and benefits derived from individual wells generally increased, and the effectively irrigated cultivated land area rose to 98 percent. Formerly, when everybody "ate out of a large common pot" in the management of labor at Lufang Brigade in Shimensong Commune, three of seven pump wells were filled with silt, and only a few machines were repaired regularly. Following institution of the responsibility system whereby responsibilities were assigned households on a large scale, not only did commune members restore to operation the pump wells that had been in a deep sleep for many years, but they also contributed their own money to sink 15 pump wells and to buy more than 30 diesel engines and electric motors, and they cleared debris from 8 li of trunk and branch ditches. These water conservancy facilities showed their mettle during this year's struggle against drought. In the process of spreading this representative experience, the County CCP Committee and county government directed attention to consultation among commune and brigade cadres and the masses with no "arbitrary uniformity," and no "formalism," genuinely helping communes and brigades as well as peasant households solve concrete problems in the management of farmland water conservancy. In addition to sending 45 technicians from water conservancy departments into the countryside to provide guidance, the county also provided management technicians to each commune, and gave energetic support in the maintenance and repair of equipment. During this spring's struggle against drought, throughout the county all kinds of farmland water conservancy facilities played a role so that irrigation could be maintained on more than 80 percent of the watered area. Three hundred fifty thousand mu of wheatfields were watered three times, and a good harvest reaped from them. Most cottonfields were irrigated to insure full stands of sturdy seedlings. The broad masses of people said that to have such a good harvest in a disaster year resulted from the encouragement that production responsibility systems provided and the help of farmland water conservancy facilities.

TECHNIQUE OF SUCCESSIVE CROPPING OF WHEAT, COTTON DESCRIBED

Jinan DAZHONG RIBAO in Chinese 21 Apr 82 p 3

[Article: "Put Into Effect Double Cropping of Wheat and Cotton and Increase Economic Benefits"]

[Text] Linyi County's carrying out the cropping experiment of producing both wheat and cotton crops on the same field in one year has achieved remarkable economic results after being popularized throughout the entire area, thereby opened up a new path for developing cotton production.

Under the direction of state planning, this county faces the new problem of how to guarantee a continuous increase in the grain production and cotton production simultaneously so as to increase economic benefits. Under the leadership of the county central committee and the county government and with the support of the concerned departments at the upper levels, the county's agricultural science institute, proceeding according to the actual situation and beginning in 1979, has carried out an experiment of changing the spring sowing of cotton to summer sowing, then and from single cropping to double cropping of wheat and cotton within the same year. Three years of this experiment have proved that putting into effect a system of having two crops and two harvests in the same year, one each of wheat and cotton, has remarkable economic results. Last year, we sowed summer cotton on 40 mu of experimental fields, on which our 1st crop, of wheat, yielded 712 jin per mu; we then grew cotton, which yielded 121 jin per mu of ginned cotton. Throughout the county the demonstration of this technique was extended to cover 2,834 mu, on which the 1st crop of hweat yielded an average of 426 jin per mu, and the summer cotton yielded an average of 103 jin of ginned cotton per mu.

In order to put into effect this system of growing one crop of wheat and one of cotton in the same year, it is necessary to do a good job of pairing good varieties. The varieties of summer cotton must possess the characteristics of a short growth period, early ripening, and high yield and superior quality. The county's agricultural science institute, following only 2 years of the experiment, was able to screen an excellent variety that adapts well to the local condition--"zhongmiansua No 10 cotton." This variety is sown during the first third of June, the bolls open at the end of September and it is harvested at the end of October. The growth period only lasts 140 days, and it possesses the excellent characteristics of early flowering, quick boll formation, with few spindle branches, and tight and dense stem types, appropriate for close planting, little effected by insect pests and diseases, and easy to manage. Not only does it produce a comparatively large quantity, but the quality of the fibers is comparatively good. The Beijing Fiber Inspection Station and the Jinan national Cotton Mill No 4 have already woven on the trial basis into 32-count yarn; th- quality standard was as high as 2,700 fen, and the fiber length was between 29 and 31 mon. The variety of wheat that it was paired must be sowed at the end of October or the beginning of November, and is harvested at the beginning of June. Two years of experiments have demonstrated that the wheat variety #767-57 possess the excellent characteristics of late sowing, early maturing, high yield, and good quality, and at present is a rather good variety for being paired with cotton for double cropping.

Linyi County's experimental system of the successive cropping of wheat and cotton is obviously superior. It has changed the area's planting structure for food grain and cotton production, is good for solving the contradiction of food grains and cotton being in competition for land, has yielded comparatively good economic benefits, and is enthusiastically welcomed by the masses. This year, the county as a whole plans to plant over 100,000 mu of summer cotton.

COMMENTARY ON PRESENT, URGENT NEED FOR MORE FARM MACHINES

Jinan DAZHONG RIBAO in Chinese 19 Apr 82 p 2

[Commentary: "Under the New Economic Circumstances, Do a Good Job of Farm Machines Supply Work"]

[Text] The work of supplying farm machinery is an important component part of the entire enterprise of agricultural mechanization, a link and bridge for combining industrial and agricultural production, and a logistics department in the direct service of agricultural production. Actively doing a good job of supplying farm machinery and its spare parts has extremely importance significance concerning the rate of the arrival and condition of the machinery, its utilization rate, bringing the effects of agricultural mechanization into full play, and promoting the development of agricultural production.

The work of supplying agricultural machinery must maintain the direction of socialist management, adhere to the general guiding principle of "developing the economy and protecting supply," and firmly establish the viewpoing of serving agricultural production. At present, the total motive power of our province's farm machinery has reached over 20 million horsepower, distributed among all the communes and brigades, and families and households in the rural areas. The supply of farm machinery involves a broad area, and large quantities; and the task is both arduous and glorious. Doing everything we possibly can to guarantee supply is the direction of our work in supplying farm machinery, and is also the minimum requirement. Experience proves that if only to persevere in proceeding in everything, on the basis of the needs of agricultural production, and overcome the attitude in management of making an all-out effort when there is much profit, working less diligently when there is little profit; and not at all when there is no profit; will we be able to do a good job of supply work. If we pursue only high profits for the enterprises, then the tendency to fear overstocking and not to fear selling out, as well as that of not paying enough attention to quality, is sure to appear. This will have a negative effect on agricultural production, and ultimately cause the enterprise of agricultural mechanization to suffer economic loss. Our placing importance on the quality of the agricultural machines produced will have a bearing on the whole question of whether or not the work of supplying farm machinery will be able to maintain the viewpoint of production and the viewpoint of the masses. We definitely must set up a sound organizational structure for quality control, assign quality control personnel, strictly check on quality and ensure that the quality of the products is up to the standard required for their being bought and sold, conscientiously implement the policy of the "three guarantees" for agricultural machinery products, and thoroughly fulfill our responsibility with respect to the products to be marketed.

After systems of responsibility for agricultural production were put into effect, the objective of the service of supplying farm machinery underwent a great change, and it had to serve both the collective and all the individual families and households. The masses' need for farm machinery also underwent a change, and the different areas and units all required different types, specifications, and models of farm machinery. Areas where conditions were comparatively good required an increase in large and medium-sized machines, and a large number of areas required an increase in the supply of small machines and semimechanized farm implements. In the past, agricultural machinery products were produced and distributed to the various levels according to a single, unified plan and, whether good or not, all were needed. Nowadays the peasants have acquired the right to take the initiative with regard to production, and what, when, and how much is to be sold are all determined by the peasants themselves. These new circumstances all pose new requirements in the work of supplying farm machinery. Since the beginning of this year in particular, due to the continuous improvement of the rural economy, the enthusiasm of the collectives and commune members to improve production is at an unprecedentedly high level, and the momentum of the increase in the quantity of farm machinery sold is comparatively obvious. If we want to accomplish the guaranteeing of supply, then we must step up our investigation and study, adapt our supply measures to local conditions by selling the various agricultural machines and tools precisely where the specific markets for them are, and satisfy the masses' needs. At the same time, we must improve our management practices, and improve the quality of service. In everything we do, we must proceed from the basis of what is beneficial for production and convenient for the masses; persevere in developing the effective supply methods of ordering goods in advance, supplying goods by telephone, sending goods into the rural areas, working day and night shifts, giving demonstrations on the spot, and providing mobile guidance, maintainance and repairs and make a great effort to develop supply and technical service activities. We must carry out a civilized managerial style, by treating our customers courteously, provide excellent quality service, and accommodate the masses.

FARM PRODUCTION MATERIALS IN SHORT SUPPLY

Jinan DZZHONG RIBAO in Chinese 18 Apr 82 p 3

[Article: "A Look at the New Characteristics of This Year's Argicultural Production Materials Markets"]

[Text] In our province a new aspect of the continued, large-scale rises for agricultural production materials has occurred in the market. Sales volume for the first 2 months of this year is also 30.9 percent higher than for the same period last year. Included in this, machinery for spraying pecticides and plastic film for agricultural use increased by 90 and 50 percent respectively; chemical fertilizers, and medium- and small-sized farm implements increased by 30.4 percent; the quantity of farm chemicals, iron wire, diesel oil, and sold also increased by quite a lot. This is something that has not happened for many years. However, from the point of view of the present situation of the production, supply, and marketing of agricultural production equipment, there are still many problems. Market characteristics for some of the principal commodities are:

The market for phosphate fertilizers has become brisk; this high-quality production is in great demand. In recent years, following the development in agriculture of scientific methods, of tilling the soil, surveying the soil, and applying the fertilizers, in the various areas there everywhere occurred the problem of the composition of the soil having a serious lack of phosphates. Although the quantity of phosphate fertilizer that has been supplied in the first season of this year has increased by nearly 50 percent compared with last year, nevertheless from the point of view of the situation of the [quantity of] fertilizer needed by the various areas and the sources of the commodity controlled by the commercial departments, our province's production of high-quality phosphate fertilizer this year will far from meet the needs of agricultural production.

The quantity of small- and medium-sized farm implements required has risen dramatically, and some items are in extremely short supply. Following the implementation of systems of production responsibility in agriculture, the quantity of small- and medium-sized farm implements needed in rural areas increased remarkably. In particular, every family and household wanted to acquire more hoes, sickles, shovels, pickaxes, drills, harrowing and dragging plows, pitchforks, baskets, brooms, wooden winnowing spades, etc. As a result, the quantity supplied in the first two months of this year has increased 30.4 percent over the same period last year. However, the present situation of the supply demands of the various locations throughout the province indicates that there is a short supply of some major brands and varieties, and some brands are not up to standards. There are gaps in the demands and the availability, and the needs of production cannot be met. In particular, the need for hoe blades and hoe hooks cannot be met. The major cause is that these products must be forged by human labor, and their production requires much labor, and a high outlay of materials, with little profit. We must adopt measures as soon as possible to realize the mechanization of agriculture.

Sales of thin plastic film for agricultural use have gone from slow to brisk, with supplies getting tighter by the day. Since the beginning of spring, the quantity of thin plastic film for agricultural use needed for raising seedlings for cotton and flue-cured tobacco has grown larger and larger. Last year, over 10,200 tons were supplied to the entire province, and this year the estimated required supply will be over 12,000 tons. Based on arrangements contained in the state's plans, this year the commercial departments must purchase 6,340 tons from industry. For the first three months of this year however, due to all kinds of causes industrial production has simply not turned the goods over to the commercial department. Although the supply and marketing department has imported over 7,000 tons from outside the province, that is still not enough to change the tight market situation. Hereafter we must get a good hold on production as soon as possible, and do a good job of solving the problems of planned allocation and supply, within our province.

BRIEFS

AGRICULTURAL MACHINERY ENTERPRISES--Following the establishment of all types of systems of production responsibility in the countryside, over the last few years a new aspect has appeared in the development of the enterprise of agricultural machinery in our province. Total motive power of farm machinery provincewide is over 20 million horsepower, an increase of more than 6 million horsepower over 1978. Characteristics of the development of agricultural machinery are: the demand for hand-support tractors and small-sized irrigation and drainage machines increases by a big margin; the ratio for an increased demand of the processing machinery for agricultural and sideline products clearly on the rise; the quantity of the farm machinery in the economically better off prefecturss, such as Yantai and Weifang is steadily rising; and a "farm machinery fever" has started in the four areas of the northwest where the economic foundation originally was poor. At present, throughout the province as a whole the area farmed by tractor has increased by over 240 million standard mu compared with 3 years ago; the area plowed by machine has increased by over 12 million mu; the area in which wheat is sown by machine has increased by 60 percent; and the area which is harvested by machine has increased 2.1 times. FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

I. GENERAL INFORMATION

EARLY CONTROL OF RURAL INDUSTRIAL POLLUTION URGED

Beijing ZHONGGUO NONGMIN BAO in Chinese 15 Jul 82 p 1

[Article: "Earliest Action Must Be Taken To Control Rural Industrial Pollution, City and Countryside Construction and Environmental Protection Office Officers-in-Charge Point Out"]

[Text] The correspondent has obtained the following from the City and Countryside Construction and Environmental Protection Office. Environmental pollution currently shows a tendency to spread from the cities to rural villages in China. Officers-in-charge at this office pointed out that Suzhou Prefecture in Jiangsu Province was once a storied "land of fish and rice," but with the development of rural industry during the past several years, the waters of the network dominated by the Grand Canal have become polluted. Some places have been polluted by wastes from electroplating to the extent that their farm and aquatic products cannot be eaten. Shaoxing County in Zhejiang Province, with its green mountains and clear waters, has been seriously polluted by the effects of printing and dyeing, electroplating, and paper making plants. Nationally many rural industrial enterprises still lack facilities for the prevention and control of pollution, and frequently one small plant may pollute a river or a village or town. In many places, large and medium size industrial plants consign or transfer to commune and brigade industries for use in production the toxic and dangerous goods that they do not want to produce or process, leading to the toxification of the "country-side." Such a shifting of pollution not only harms the physical health of the broad masses of peasants, but as a result of the pollution of agricultural products, it returns to harm urban residents. Once rural villages become polluted, the investment required to clean them up is higher and difficulties greater. Therefore, effective action must be taken earliest to bring it under control.

The officer-in-charge at the City and Country Construction and Environmental Pollution Office strongly emphasized that the key to effective control of rural industrial pollution lies in all levels of the people's government conscientiously carrying out the pertinent regulations and the spirit of "Decisions on Further Intensification of Environmental Protection Work During the Period of National Economic Readjustment," and "Various Regulations on Commune and Brigade Enterprises Carrying Out National Economic Readjustment Programs," issued by the State Council, strengthening of leadership in rural industrial enterprises, and taking a firm grip on the following several tasks:

1. Need for Equitable Distribution. The building of environment polluting enterprises is not permitted upwind from cities and towns, living and residential areas, water source preserves, famous antiquities, scenic tourist sites, warm springs, convalescent areas, and nature preserves. Where such have been built, regulations are to be formulated to bring them under control within a limited period of time. Where no solution is possible, they are to be closed, suspended, merged, or retooled.

2. Strict Enforcement of the "Three Concurrent" Regulations. For all newly built, converted, or expanded enterprises, or enterprises retooling their production, pollution control equipment must be designed, built, and start up concurrent with the main project. Projects, lacking equipment to control pollution may not be constructed or, if constructed, they may not go into operation.

3. Need To Readjust Product Composition. Industries that are of low toxicity or non-toxic and that do not pollute or only slightly pollute the environment are to be advocated, and production that uses everything is to be encouraged. The practice whereby large and medium size industrial plants and cities pass off to communes and brigades for their production toxic and harmful products that they themselves do not want to produce or process is to be guarded against.

4. Reorganization of Existing Polluting Units. Clean-up action should be taken for the "three wastes" [waste gas, waste water, and industrial residue] in order to reduce pollution damage. Units that discharge the "three wastes" beyond nationally fixed standards are to be charged pollution discharge fees in accordance with regulations. For enterprises that waste large quanitities of resources and energy and seriously pollute for which no solution is available, in the course of reorganization they should be closed, suspended, merged or retooled. In addition, vigorous efforts should be made to promote comprehensive use of the "three wastes," and to promote the experiences of advanced units who protect the environment.

EXHORTATION ISSUED ON RAINY SEASON AFFORESTATION

Beijing ZHONGGUO NONGMIN BAO in Chinese 22 Jul 82 p 1

[Article by commentator: "Firmly Grasp the Opportune Time To Afforest During the Rainy Season"]

[Text] The rainy season is a very fine season in which to plant trees for afforestation. Firmly grasping this favorable opportunity to do large-scale planting of trees for afforestation holds important significance for fulfillment of afforestation tasks for the year as a whole and for hastening the greening of the motherland.

China's forest resources are scant and very unevenly distributed, but throughout the country there are more than 1 billion mu of barren mountains and wasteland flats suitable for forests, as well as a large amount of unused land in the four besides [besides streams, roads, villages, and houses] where trees can be planted. We must carry forward the spirit of the foolish old man who moved the mountain, perserve in the planting of trees every year and afforestation in every season, and adapt general methods to local situations, taking every favorable opportunity to do large-scale planting of trees for afforestation as the only way in which to rapidly bring about the greening of the motherland and change the backward state of affairs in forestry with all possible speed.

During the rainy season when the soil is wet and humidity is high, the survival rate for afforestation is high. Areas of north and northwest China have been traditionally in the habit of afforesting during the rainy season. In these areas, the ratio of rainy season afforestation is very great in relation to afforestation for the year as a whole. Consequently, a good job of rainy season afforestation plays an extremely important role in fulfillment of afforestation tasks for the entire year.

The key to doing a good job of rainy season afforestation lies in solid preparation. The rainy season is short and strongly seasonal in character; it is necessary to do advance planning of forestlands, prepare the soil, grow seedlings, conduct technical training, arrange for worforces, and such preparatory work. Once the rainy season comes, opportunity has to be taken and concerted efforts made to finish the job; otherwise, a fine opportunity may be lost. This year the rainy season came early in North China, so in order not to miss the opportune moment, vigorous efforts to organize the masses have to be made to begin rainy season afforestation. In places in which the rainy season has not yet arrived, preparatory work of all kinds should be taken firmly in hand, and rainy season afforestation tasks assigned. All jurisdictions should do as in the case of springtime afforestation, devoting attention to rainy season afforestation now.

All levels of party and government leaders and departments concerned should strengthen leadership of rainy season afforestation and take a genuinely firm grip on rainy season afforestation. Leadership cadres have to fix work responsibility for individual tracts, and themselves lead the masses in the planting of trees for afforestation. Forestry policies are to be conscientiously implemented to stimulate the enthusiasm of the broad masses of people. Commune and brigade collective afforestation should carry out centralized leadership and centralized planning, with the adaptation of general methods to specific situations and distinction among different circumstances to put into effect various forms of forestry production responsibility systems that link results in afforestation to the calculation of compensation. Contracting may be done with commune and brigade forest farms, specialized teams, specialized units, or specialized households. Alternatively, contracting of full responsibility may be done on an individual household basis within rights, responsibilities, and benefits in contracting the transplanting of seedlings and insuring their survival clearly defined. At the time, individual commune members should be actively induced to plant trees for afforestation on privately retained mountains or in places designated by communes and brigades. A good job of rainy season afforestation also requires attention to science and emphasis on genuine benefits. A strict system of inspection and examination before acceptance has to be instituted to maintain quality and quantity so that every seedling planted survives and every tract afforested remains afforested.

In addition to doing a good job of rainy season afforestation, all jurisdictions should also make full use of the favorable conditions of soil friability following the rains to devote strict attention to readying the land in preparation for afforestation this fall or next spring. In order to consolidate results from afforestation, all jurisdictions should intensify forest trees protection and care and nurture of young forests.

MORE COUNTIES BECOME PROSPEROUS IN COUNTRYSIDE

OW181435 Beijing XINHUA in English 0722 GMT 18 Aug 82

[Text] Beijing, 18 Aug (XINHUA)--A growing number of counties are becoming well-off in China's countryside, according to the Ministry of Agriculture, Animal Husbandry and Fishery.

According to information issued by the ministry following a national meeting on rural income, China in 1981 had 49 counties where annual peasant income from their collectives averaged more than 300 yuan for each person. There were 22 counties with such rural income level in 1980 and only four in 1979.

In recent years, China has adopted policies encouraging peasants to become prosperous by hard work. According to a sample survey of 18,500 peasant families made by the State Statistical Bureau, the 1981 per-capita income of the peasant, including income from the collective and domestic sidelines, was 67.3 percent over that in 1978. And in some areas peasant income doubled in 3 years.

Though the 49 top-earning counties account for only 2.3 percent of China's 2,100 counties, their example demonstrates that peasants in all areas, pastoral or mountainous areas or plains, can raise their income through hard work.

Nearly 11,000 production brigades had an average annual income per rural capita of 300 yuan from the collective in 1981. The number of such top earning brigades was almost double that of the preceding year.

Madoi County of Golog Tibetan Autonomous Prefecture in Qinghai Province, 4,500 meters above sea level, was the highest income earner of all counties in China last year. It increased the total number of its cattle and sheep at an average annual rate of 17.2 percent between 1979 and 1981.

In 1981 the herdsmen there delivered 150,000 newborn animals. Per capita income of the county's herdsmen derived from their collectives reached 475.3 yuan last year. The days when the herdsmen wore raw sheep skins all year round are gone. Most herdsman families have bought radios, sewing machines and carpets, and 96 percent of them have bank savings.

Last year, Tibet had nine counties where each person earned an average of over 300 yuan from the collective, the largest number of high earning counties in all China's provinces and regions. The prosperity of these counties is attributable to the state policies adopted to boost Tibet's economy. Included are: Exemption from taxes, increased purchase prices for livestock products and providing peasants and herdsmen with insecticide and free veterinary services.

Among the nine Tibetan counties are Gar County and Rutog County on Ngari grassland 4,000 meters above sea level and Yadong County in the Himalayas. Yadong County, with limited farmland, has expanded its timber industry in addition to engaging in agriculture and animal husbandry.

Nanhai County in the densely-populated Pearl River delta of Guangdong Province, with a population of 800,000, doubled its total industrial and agricultural output value in 3 years. Peasant income rose to the same extent. Since 1979, the county has expanded aquatic products breeding, silkworm raising, enlarged areas of sugar cane and other economic crops, and set up small labor intensive enterprises to produce fireworks, bamboo, rattan articles and other products. Income from small enterprises in 1981 accounted for 60 percent of the total income of rural collectives.

Collective accumulation funds are also going up. The rural collectives last year allocated 15 percent of their total income for expanded production and public welfare.

Meanwhile, the number of poor counties and rural collectives has dropped, according to the ministry.

CSO: 4020/162

COUNTRY EXPANDS DIVERSIFICATION OF RURAL ECONOMY

OW240205 Beijing XINHUA in English 1246 GMT 23 Aug 82

[Text] Beijing, 23 Aug (XINHUA)--Rural sideline undertakings are an increasingly important source of income for Chinese peasants and are providing employment for growing numbers of people.

Animal husbandry, forestry, rural workshops and other sidelines have expanded faster than crop cultivation in the past few years. Their annual output value went up 31 percent between 1979 and 1981, compared with the 11.5 percent for field crops.

"Only by increasing commodity production can the rural areas become well off," said Li Min, an official in charge of rural sideline undertakings in east China's Shandong Province.

For years after liberation, emphasis was put primarily on grain although the area of farmland per capita is limited. Yet there are rich resources for diversifying the rural economy on the vast expanses of mountains, hills, grasslands and inland and coastal waters. "The diversifications of the rural economy will enable the peasants to turn out more and a greater variety of commodities for sale," Li Min said.

The diversified undertakings have been made possible by the raised efficiency of the peasants following adoption of the responsibility system since 1979, Li Min said. According to agricultural departments, in many areas 20 to 30 percent of the rural labor force is being released from farm work, and this provides abundant manpower for expanding sidelines.

For instance, in Tonglu County of Zhejiang Province, 16,000 people are being drawn from farming to collective enterprises this year. This will bring the total number of people employed by the enterprises to 42,000, accounting for 30 percent of the rural manpower.

The present policy calls for unrelaxed efforts to expand grain production while encouraging other rural undertakings.

The Agricultural Bank of China is issuing 800 million yuan in low interest agricultural loans this year, specially for the construction of production centers devoted to rural sideline undertakings. In addition, much of the agricultural loans granted by provincial branches of the bank to rural collectives and peasants are also used for the diversification of the rural economy.

The rural sidelines are being expanded through two channels, collective and household undertakings.

Rapid progress has been made in expanding rural collective enterprises. At present about 30 million commune peasants, about one-tenth of China's rural labor force, are working in rural enterprises which include farm machinery workshops, chemical fertilizer plants, brick and tile kilns, textile mills, tailoring shops, shoe-making workshops, tea and fruit gardens and livestock farms. The enterprises turned out products worth 63,300 million yuan in 1981, roughly one-third of the total rural income from all sources last year.

In addition to the collective undertakings, the peasant families are raising more livestock, poultry and rabbits as domestic sidelines. Embroidery and arts and crafts are popular among peasant families in areas with such traditional skills.

With the diversification of the rural economy and the expansion of trade, townships with clusters of industrial workshops, processing mills, service trades as well as theaters and schools have come into existence in quite a number of people's communes or xiang (comprising several communes). On the Yangtze and Pearl River deltas and on the rural outskirts of Beijing and Shanghai, such small townships have sprung up in most of the communes.

Thus diversification of the rural economy is leading to a gradual change in the distribution of cities and towns in China. The new townships are becoming economic and cultural centers in the countryside.

Wang Yuchao, member of the Standing Committee of the Anhui Provincial Committee of the Chinese Communist Party, said that in Chuxian Prefecture of that province "over 30,000 young people are expected to join the rural labor force annually between now and 1990 in this area with a population of 3.3 million. They will find jobs in the countryside or in the small towns that have come into being, instead of drifting to the big cities," he noted.

CSO: 4020/162

ECONOMIC IMPORTANCE OF GRASS UNDERSCORED

Beijing ZHONGGUO NONGMIN BAO in Chinese 15 Jul 82 p 1

[Article: "North China Should Vigorously Grow Grass To Encourage Animal Husbandry To Promote Agriculture, National Grasslands Expert and Deputy Director Gansu Agricultural College, Ren Jizhou [0117 4949 0719] Suggests"]

[Text] Grasslands expert and deputy director of the Gansu Provincial Agricultural College, Professor Ren Jizhou, recently told the reporter that he believed that vigorous efforts to grow grass in North China, particularly in places having a fairly large amount of land, would both help development of animal husbandry, be beneficial to the promotion of agriculture, and would also gradually help bring about ecological balance.

Ren Jizhou said North China covers a vast area where conditions for the development of farming and the animal husbandry industry are fairly superior, but ground cover is scant; many drought disasters occur; and erosion is serious. If strengths are to be used to make up for weaknesses, simultaneously with the planting of trees for afforestation must come vigorous encouragement to the growing of grass. He said benefits from the growing of grass are numerous.

First, the grasslands are huge factories for fixing solar energy. The energy stored in organic material produced by the growing of grass throughout the world annually is roughly equivalent to the world's annual consumption of energy. This organic material greatly changes soil fertility and enriches the quality of life in the world. The organic material produced by grass is about two-thirds underground and one-third above ground. The underground portion can improve the soil, and the above ground portion makes very useful animal fodder and can be converted into mature livestock products. Gansu Province has more than 200 million mu of grasslands. Were they to be equitably used, the annual amount of meat produced would increase tremendously.

Second, grass is the ecological system's supplier of nitrogen. Pulses and pasture grasses can fix nitrogen from the atmosphere and convert it into organic matter. A single mu of alfalfa can fix about 30 jin of nitrogen in 3 years, the equivalent of almost 100 jin of ammonium nitrate. The amount of coarse protein contained in the portion of pulses and pasture grasses above ground is at least about 20 percent. This coarse protein may be directly used by animals. Thus is can be said that pulses and pasture grasses are the sources of life on earth. Many places do not devote sufficient attention to development of pulses and pasture grasses today, and this is a large problem deserving of great attention in agricultural production and for which diligent action must be taken to solve.

Third, grass plays a very great role in water and soil conservation. In places in the loess highlands with a rainfall of less than 500 millimeters, the capacity of grass to conserve water and soil is no less than that of forests. The ability of grass to soak up rainfall is virtually the same as that of forestlands. The ability of grass to bind together surface soil and prevent it from being washed away is somewhat better than that of forestlands. It can cause soil to form a granular structure that increases soil capacity to hold water. Grasslands have a far greater capacity to conserve water and soil than farmland. Many years' growing of dog's tooth grass, a member of the grass family, shows it to be 300 times more able than corn to conserve soil and water, and its ability to conserve water is about 1,000 times greater. Roots of pasture grasses that have grown for many years are about three times more numerous than from crops in general, and the area the roots cover may be from two to four times greater. The greater the area of root coverage and the larger the area of soil in contact with the roots, the greater the ability to conserve soil.

Fourth, grass greatly benefits environmental sanitation. Grasslands can absorb dust and reduce the amount of flying dust on the soil's surface. The ability of a thick growth of grass to prevent dust is more than four times greater than that of bare ground; it is strongly able to attract dust. It can purify the air, reduce environmental noise and pollution, and regulate air temperatures. Grasslands are like a thermostat in that the physiological function of grass itself causes the temperature of the grass not to rise beyond 20°C. The function of grasslands in lowering temperatures is remarkable in dry and desert areas. When sand surface temperatures reach 50 degrees, in the same area thick growths have a temperature about 10 degrees lower than the sand surface. Therefore, the more arid the place, the greater the need to grow grass.

Ren Jizhou noted that the growing of grass has to be done scientifically, the right seeds being planted in the right places, the emphasis on effectiveness. Right now most important is the taking of effective measures for positive action to win genuine results.

FAMILIES SPECIALIZE IN LIVESTOCK, OTHER PRODUCTS

OW150758 Beijing XINHUA in English 1226 GMT 14 Aug 82

[Text] Harbin, 14 Aug (XINHUA)--More than 560,000 families specialized in raising pigs, poultry, rabbits, bees, sheep and other livestock have become an important supplier of meat, poultry, furs, skins and other products in China, according to a national meeting now in session in Harbin City.

These family undertakings are generally started by experienced peasants who have techniques and management skills, and therefore have a much higher productivity than ordinary peasant households. Some educated young people, as well as residents of city suburbs, housewives and retired city workers have also started such undertakings.

Unlike an ordinary peasant household which usually keeps a very limited number of livestock and poultry, a "specialized family" may raise dozens or even over one hundred pigs, or several hundred to over one thousand chickens.

The meeting pointed out that these "specialized families" have emerged in China following the implementation of new rural policies since 1979.

Suited to the production and management levels in China's rural areas, this form of management can better meet the needs of the growing market, the meeting noted. It is easier to run such family farms than large-scale, modernized livestock or poultry farms. This form of management is a step towards specialized and socialized production and has opened a new way for commodity production, the meeting said.

Apart from "specialized families," there are "key households" in the countryside which simply raise more animals and poultry than other commune members, while still participating in normal farm work. There are now 1.77 million such households in China's countryside.

Both these "specialized" and "key" families, totalling more than two million, are now raising more than 10 million head of livestock, 58 million poultry, 12 million rabbits and more than half a million beehives, according to figures released by the meeting.

Animal and poultry raising by "specialized families" shows many advantages, the meeting said. Following their example, ordinary households are encouraged to also take up the trade, and can begin quickly and easily.

Figures from Hebei, Shanxi, and other provinces show that the livestock and poultry farms of the "specialized families" have a high rate of marketable products. These families also help spread science and techniques in the countryside.

Both "specialized" and "key" families generally are not divorced from their collective units. They get fodder from the collectives or state grain stores and sell their products to the state.

These families have quickly increased their income. Zhao Huanshuang, a peasant in Shandong Province, set up a livestock and poultry farm on a nearby mountain. His family of four raises 470 geese, 50 chickens, 40 rabbits, eight goats, two cattle and five pigs, in addition to managing six hectares of mountain forests. He received 3,600 yuan in the first half of this year and is expected to earn a total of 7,000 yuan this year. After handing a certain sum over to his production team as public fund and deducting costs, his family income is estimated to reach 4,000 yuan in the year.

CSO: 4020/159

BRIEFS

FRESHWATER AQUATIC PRODUCTION--Beijing, 10 Aug (XINHUA)--China's total freshwater aquatic production in the first half of 1982 reached 500,000 dun, an increase of 7.1 percent over the same period last year. [Beijing XINHUA Domestic Service in Chinese 0113 GMT 10 Aug 82]

RURAL INCOME, SAVINGS--According to SHIJIE JINGJI ZAO BAO [WORLD ECONOMIC MORNING NEWS], the Chinese peasants' income in 1981 increased 67 percent over that in 1978. As of the end of April 1982, total rural savings had reached 24 billion yuan. The total amount of agricultural loans offered in the first 4 months of 1982 reached 35 billion yuan. [Shanghai City Service in Mandarin 2300 GMT 8 Aug 82]

NORTHERN RURAL CAPITAL CONSTRUCTION--An experimental project to improve animal husbandry on 286 million hectares of grassland in North China, an area nearly three times as large as all of the nation's cultivated land, is now underway. The $80 million project is being carried out by the state bureau of animal husbandry and the Agricultural Bank of China, which will administer a $35 million grant from the International Fund for Agricultural Development (IFAD). Unlike most large-scale projects, which are aimed at large, state-owned enterprises, the grassland project will focus on production brigades and individual commune members in 24 representative communes. "Eighty million dollars is not much money, considering the area involved," an official at the animal husbandry bureau told CHINA DAILY. The project will pursue different goals in different areas, depending on climate and other natural conditions, the official said. Despite some initial problems with management and with handling foreign investment, the project has gone smoothly so far, the official said. In the Kundu Commune of the Alukereqin League, Nei Mongool, for example, peasants have already completed 50 percent of the required fencing and tree planting, and 15 percent of the grass planting. Well drilling and construction of animal shelters will begin soon, the official said. [Text] [HK110233 Beijing CHINA DAILY in English 11 Aug 82 p 2]

IRANIAN AGRICULTURAL DELEGATION--Beijing, 22 Jul (IRNA)--An Iranian economic mission to the People's Republic of China, led by the undersecretary of the Ministry of Agriculture and Rural Development, Dr Abbassali Zali, visited several temples and pagodas in Beijing as well as the Forbidden City and the Temple of Heavenly Peace. The Iranian mission on Tuesday met the Chinese foreign trade and economic relations minister. The Chinese foreign trade and economic minister outlined China's agricultural and commercial status and reviewed appropriate areas in which to establish mutual cooperation. He referred also to China's extensive experience in certain agricultural and industrial fields. Then Dr Zali, in turn, referred to some measures taken after the victory of the Islamic revolution of Iran to remedy the economic havoc caused by the previous regime. The head of the Iranian mission also inspected the tractor manufacturing plants and machine works. [Tehran IRNA in English 1946 GMT 21 Jul 82]

PEASANT INTEREST IN AGROTECHNOLOGY INCREASES

OW230830 Beijing XINHUA in English 0738 GMT 23 Aug 82

[Text] Beijing, 23 Aug (XINHUA)--"Wherever we go, peasants come to seek our advice, in the office and the fields and even when we attend rural fairs," said Cui Huairang, who works in an agro-technique service station in Fengyang County, Anhui Province. A college graduate who has worked there for some two decades, Cui said agro-technicians "have never been so welcomed by the peasants."

Agro-technicians trained by colleges and regular secondary agro-technical schools are to be found in almost all the peoples communes of Anhui, Shandong, Zhejiang and other major agricultural provinces.

The agro-technique service center in Banqiao District where Cui Huairang works gave technical advice to 2,200 peasants in a 3-month period. The peasants often travel to a lecture on farming techniques from miles away, bringing their meals with them.

Today, radio has a special added value for peasants in China. They switch on their sets or monitoring loudspeakers in the morning or at meal time to listen to weather forecasts, information on harmful insects and plant diseases as well as knowledge about techniques for the current farming season.

Diffusion networks reach most peasant homes and the central broadcasting station in Beijing is running a teaching program for hundreds of thousands of peasants and junior agro-technicians in all parts of the country. In addition, every province and almost every county has its own broadcasting programs on agro-techniques.

Sun Guojun, head of the science education section of the Zhejiang Provincial Agricultural Department, explained why there was such a widespread keen interest in agricultural science. Under the responsibility system, he said, an estimated five million labor groups, peasant families and peasants in the province have signed contracts with production teams for farm production or sideline undertakings. Since they are directly responsible for the results, they are avid for scientific information.

"We do whatever we can to serve them, supplying them with books, lectures, films and pamphlets on agricultural science and other technical aid," Sun Guojun said. "But with millions upon millions eager to learn, our services still fall far short of demand," he said.

Thanks to the spread of scientific information, 90 percent of the rice, wheat and cotton seeds used in Anhui Province in 1981 were of fine varieties. Hybrid male sterile rice was sown on 140,000 hectares of land last year, increasing output by 160,000 tons.

In Anhui, 4,000 courses and training classes on farming techniques were given in 1981 with an attendance of two million. In all major agricultural provinces, such training classes are sponsored at the provincial, prefectural, county and commune levels.

A popular and effective way is demonstration families which voluntarily take the lead in using new seeds and new techniques in their contracted fields, guided by local technicians from sowing to harvest. With such examples at hand, surrounding peasants need not go outside their village to get ordinary technical questions answered.

At present, 52,000 of the nine million peasant households in Anhui Province are demonstrating scientific farming on 19,000 hectares. These families are called "a great supplement" to the insufficient local technical force, as the 3,300 communes only have 10,000 government agro-technicians.

Another channel for spreading agro-techniques is for agro-technicians to sign contracts with peasants to pass on methods of pest control, seed breeding and rice and wheat cultivation.

BRIEFS

PROVINCIAL AGRICULTURE--Anhui Province has done very well this year in agriculture, forestry, animal husbandry and fishery. The province's total summer grain output may reach 10.26 billion jin, an increase of 12 percent over the same period last year, and total rapeseed output may reach 1.9 billion jin, up 47 percent from last year. In the first 6 months of the year, the province afforested 1.29 million mu of land and planted 217 million trees around villages and houses and along roads and rivers. There were 3.6 million head of large animals in stock at the end of the first half year, 17.1 percent more than in the same period last year, and 1.88 million hogs were sold to the state, up 16.7 percent from the same period last year. PEASANTS' INCOME--Beijing, 16 Aug (XINHUA)--A survey of a cross-section of peasant families in suburban Beijing showed that their income increase in the last 3 years has surpassed the sum total increase in previous 21 years, according to the city's statistics bureau today. The survey, conducted over 525 households shows per capita income averaged 361.44 yuan in 1981, up 136.64 yuan over 1979. The average annual increase is 45.55 yuan between 1979 and 1981, as against 4.24 yuan in the previous 21 years. According to the statistics, the peasants' income from collective economy accounted for 71.9 percent of the total in 1981. Among the 525 families, 175 have an annual per capita income over 400 yuan in 1981, 49 over 500 yuan and 5 over 1,000 yuan. The statistics showed that families with annual per capita income over 300 yuan accounted for 61.9 percent of the sampling families in 1981, while those with annual per capita income under 150 yuan was only 4.2 percent in 1981. An official for the statistics bureau attributed the increased income to higher state purchasing prices for farm produce and sideline products, job responsibility system, the development of diversified economy run by communes and brigades, flourishing household sideline production, and more wage earners in these families. The statistics said 22 of the 525 families had an annual per capita income less than 130 yuan. [Beijing XINHUA in English 1232 GMT 16 Aug 82]

FLOOD CONTROL STRENGTHENED BY RESPONSIBILITY SYSTEM

Beijing ZHONGGUO NONGMIN BAO in Chinese 18 Jul 82 p 1

[Article: "'Double Contract' Responsibility System Manifests Formidable Power in Resisting Disasters. Jianyang Prefecture Cadre and Masses Solidarity Following Flood Disaster Revives Production Rapidly"]

> [Text] Editor's Note: This year some prefectures in several southern provinces were stricken with flood and waterlogging disasters. This was nothing out of the ordinary. Considering China's large size, it is difficult not to have a disaster in some part of it. What is so moving is that as a result of establishment of rural production responsibility systems, not only did peasant efforts in production become great, but in combat against disasters as well, they brought into play a valiant and tenacious spirit of masters in their own house. The emergence of this new situation and new atmosphere has demonstrated that policies since the Third Plenary Session of the 11th Party Central Committee have genuinely brought about fundamental changes in rural villages, and has shown the formidable power of production responsibility systems in conquering natural disasters. The several reports carried in today's newspaper on combat against disasters somewhat reflect this new situation, and readers will feel full of confidence and that prospects are bright.

In the face of a major flood disaster in mid-June, commune and brigade cadres and masses in Jianyang Prefecture, Fujian Province united as one to fight disaster and rescue from disaster in a demonstration of the formidable power produced by a combination of the superiority of collectives and individual initiative following "double contracting" whereby output quotas are based on households and households assume full responsibility for task completion.

In the rural villages of Jianyang Prefecture, where "double contracting" responsibility systems have been instituted, the rice had grown better this year than last. But in mid-June, several days of torrential rains caused houses to collapse, washed away fields with their growing crops and caused a serious disaster. No sooner had the floodwaters receded when every jurisdiction in the prefecture lost no time in beginning to rescue production, making concerted efforts to wash off plants, put plants back in place, work harder and add more fertilizer, rush plant and change plantings, and rush repairs on water conservancy facilities. In Shuikou Production Brigade in Guangze County, commune member Chen Shixue's [7115 6108 1331] house collapsed and his furniture and farm implements were washed away, causing losses of more than 3,000 yuan. But as soon as the waters receded, he went into the fields to press the seedlings back in place and wash off the crops. According to incomplete statistics, following the disaster 487,000 commune members in the prefecutre went into the fields to wash 413,700 mu of plants and to do extra work in adding fertilizer to 701,900 mu, to make additional sowings of more than 400,000 jin of late crop seeds, and to give strict attention to the prevention and control of diseases and insect pests.

After fighting the flood and doing rescue work, many communes and brigades immediately studied measures for providing for the masses and reviving production. Chengxiao Commune in Shaowu County collected 59,000 yuan from collective sources, and commune members contributed 25,000 yuan for self help to solve the livelihood problems of seriously hit households. All jurisdictions also equitably solved problems of responsibility for and remuneration of costs involved in rescue efforts. Some communes and brigades decided in the fight against disaster to institute the principle of a combination of centralization and contracting, with commune members themselves being responsible for doing the work on the fields for which they had contracted responsibility that were not greatly damaged by the disaster, records being kept on field plots that had been completely destroyed for year end unified study and solution. Farmland capital construction projects in any given production team were to be taken care of through central organization by the production team. Projects involving several production teams would be undertaken through production brigade organization. Where commune members' houses had collapsed, either near neighbors would help each other or the production team would arrange to send voluntary help from one to another in turn to provide assistance. Thus, mass enthusiasm for revival of production was very high, and some commune members voluntarily banded together to restore ditches and fields.

In recent days, Jianyang Prefecture has entered the "double contracting" season. For the time being commune members have put aside the repair and building of houses to devote themselves actively to rush harvesting and rush transplanting. As of 10 July, 56,000 mu of the early rice crop had been harvested in the prefecture, and transplanting of seedlings for the late crop was being done at the same time.

BRIEFS

NINGXIA, GANSU WHEAT HARVEST--Beijing, 29 Jul (XINHUA)--Gansu Province in northwest China expects to harvest 2.9 million tons of spring wheat and other summer grain crops this year, nearly ten percent more than last year, according to the provincial statistical bureau. Spring wheat to be gathered on 330,000 hectares in the Gansu corridor, the province's major grain producing area, is estimated at 1.15 million tons, a ten percent increase over 1981. Hetao Plain, a major grain producing center in neighboring Ningxia Hui Autonomous Region, harvested 490,000 tons of spring wheat this year on 100,000 hectares of farmland, nearly ten percent more than the 1981 record level. The good harvest is due to the institution of the responsibility system, adoption of fine wheat strains, scientific application of chemical fertilizer and increased use of herbicides. [Text] [OW010433 Beijing XINHUA in English 0727 GMT 29 Jul 82]

WHEAT HARVEST--Gansu Province's Liangdang County has reaped a good wheat harvest in 1982. By 10 August this county had stored some 3 million jin of wheat, overfulfilling the summer grain procurement task. [Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 14 Aug 82]

LINZE COUNTY WHEAT HARVEST--Gansu Province's Linze County reaped a bumper wheat harvest on 120,000 mu of farmland. The total wheat output reached 94 million jin, an increase of 28 percent over the 1981 figure and 10 percent over that of 1980 when the wheat harvest reached an all-time high. [SK191337 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 18 Aug 82]

GRAIN PROCUREMENT--Heshui County in Gansu Province reaped a bumper wheat harvest this year and peasants enthusiastically handed over the wheat to the state. By 10 August, the county had overfulfilled the summer grain procurement plan by 6,700 jin. [Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 18 Aug 82]

CHENG COUNTY WHEAT HARVEST--Cheng County, Gansu Province, has reaped a bumper harvest on its 270,000 mu of wheatfields in 1982. The total wheat output has reached 84.83 million jin, an increase of 38 percent over 1981. [SK161152 Lanzhou Gansu Provincial Service in Mandarin 1100 GMT 15 Aug 82]

LIVESTOCK PRODUCT PROCUREMENT UP--Gansu Province saw a large increase of livestock products during the first half of 1982. During the period, the province procured 54,000 cattlehides, an increase of 1.3 percent over the same period last year; 268,000 sheepskins, a 75.2 percent increase, and 40,200 goatskins, an 88.7 percent increase. Sheep's wool and cashmere also increased by a large margin over the same period last year. [Excerpt] [Lanzhou GANSU RIBAO 27 Jul 82 p 1]

MAJORITY OF GUANGDONG'S RURAL POPULATION STILL RELY ON CONTAMINATED WATER SOURCES

Guangzhou NANFANG RIBAO in Chinese 12 Jun 82 p 1

[Article: "During the Past 2 Years 3 Million People in Province's Rural Villages Now Use Clean Water Showing Improvement in Peasant Standard of Living and Cultural and Scientific Standards; Provincial Government Convenes Conference on Rural Water Improvement, Decides to Hasten Pace of Water Improvement Work To Solve Within 3 Years' Time the Problem of Drinking Water Sanitation for 8 Million Rural Population"]

[Text] The Provincial People's Government recently convened a provincial work conference on water improvement at Zinhui. The conference decided to address the problem of sanitary drinking water for 2 million members of the rural population this year and for 8 million within 3 years.

This conference was the first provincial work conference convened by the Provincila People's Government on water improvement. Attending the conference were persons in charge in all prefectures, counties, and municipalities to a total of more than 140. Deputy Provincial Governor Yang Kanghua [2799 1660 5478] gave a speech.

The conference summarized and exchanged experience. Ever since the Provincial People's government handed down directives on doing a good job of improving rural drinking water sanitation in 1980, all levels of the people's government have diligently carried them out to give vigorous impetus to development of work to improve water in rural villages of the province. As a result of these 2 years of efforts, 3 million people in the province's rural villages now use clean water, and more than 70 percent of these have running water.

The conference acknowledged that practice everywhere has shown that in order to do a good job of rural water improvement, it is necessary first of all to increase understanding of the importance and urgency of rural water improvement work, and to strengthen leadership of this work. At the present time, about 13 million people in the rural villages of the province get their drinking water out of rivers, ditches and ponds, and 1.5 million people drink highly fluoridated water or brackish water, or have inadequate water. Because drinking water is not clean, communicable intestinal diseases increase year by year. There have been cases of pesticide poisoning and food poisoning, and the tumor incidence rate rises year by year. That so many peasants drink contaminated water; more than 30 years after Liberation is an important matter that should arouse the extreme concern of all levels of the people's government. A good job of water improvement is an indication of improvement in the living standards and in the cultural and scientific levels of the peasants. It is also a benefit that the people can see and touch right away; it is something everyone wants. For ecample, Shantou Prefecture party and government leaders devoted considerable attention to the task of improving water, and took firm action. During the past 2 years the prefecture has completed work on more than 5,200 projects to improve the water, thereby benefiting 610,000 people. Now more than 70 percent of the people in eight of the prefectures 13 counties and municipalities have clean drinking water. Formerly Foshan Prefecture did not act firmly enough, but last year acted to complete construction on running water projects that benefited 360,000 people, making it the prefecture in the province with the finest accomplishments in improving water last year.

The conference acknowledged that improvement in rural village water has broad ramifications and required all departments concerned to take active responsibility, to divide tasks and cooperate, each discharging his obligations to the maximum extent possible as the way to do a good job.

The conference agreed that rural water improvement is a job for public utilities and is a collective welfare endeavor for the masses. During a time when the national economy is in somewhat strained circumstances, improvement in rural water must adhere to a program of self-reliance with "people acting with public support action by the people being paramount." Statistics from Foshan Prefecture show that last year the prefecture completed construction on 228 running water projects, investing a total of somewhat more than 11.13 million yuan, 66.4 percent of which came from funds contributed by communes, brigades, and individuals, with the state providing 16.2 percent as a support subsidy, overseas Chinese and compatriots in Hong Kong and Macao providing 11.4 percent, and industrial enterprises contributing six percent. This experience is a very good one that can hasten improvement in rural water under current circumstances in which the country is still fairly poor and the peasants are not yet very rich.

POINTERS GIVEN ON INCREASING HYBRID RICE YIELDS

Guangzhou NANFANG RIBAO in Chinese 17 Jun 82 p 2

[Article by Li Shanfa [2621 9810 4099], Provincial Department of Agriculture: "Great Prospects for Development of Late Crop Hybrid Rice"]

[Text] Last year Guangdong Province grew 2.83 million mu of late crop hybrid rice, more than double the amount for the same period in 1980. Though the weather was abnormal, with somewhat too much rainfall and insufficient sunshine, plus damage from torrential typhoon rains and the cold dew wind during the mid and late stages of growth, nevertheless, with a rational crop pattern, proper arrangement of hybrid combinations, and adoption of a series of commensurate farming practices, all jurisdictions were able to obtain increased yields, which were generally 100 jin more and as high as more than 200 jin more per mu that from conventional varieties.

Production practice during the past several years has shown that promotion over wide areas of late crop hybrid rice is an important means of capitalizing on strengths and downplaying weakness to speed up the realization of consistently high grain yields. Today there are many conditions favoring development of late crop hybrid rice in Guangdong Province. First of all, hybrid rice has stronger growth heterosis than conventional rice; its photosynthesis is strong, its accumulation of material great, its panicles large and grains numerous; its per thousand grain weight heavy, its potential for increased yields great, and yields of more than 1,000 jin per my are easily obtainable from it. Secondly, following several years of selecting combinations, superior variety combinations Shanyou No 6, Weiyou No 6, and Shanyouke 30 have been selected. They are all characterized by good plant shapes, strong heteroses, high fruiting rates, strong resistance, strong resistance to bacterial blight and leaf hoppers, and suitability for growing as a late rice crop. Third, hybrid rice ripens early making it possible to avoid the cold dew wind. The cold dew wind is the main calamitous weather for the late rice crop, but it occurs during October in most years. If hybrid rice is sown in late June or early July and transplanted in late July or early August, it can be in full head by the end of September, and thus the late rice crop would have about a 90 percent chance of escaping the cold dew winds. In this way the passive situation could be evaded in which light sensitive types have to go through the stage of short days of sunshine in the fall in order to produce panicles, frequently encountering cold dew winds as a result. This would play a major role in changing the situation of low and inconsistent yields from the late rice crop.

Guangdong Province has accumulated some good experiences in the development by hybrid rice, but attention to the following several points is still required to farm it. (1) Need to guarantee a safe full head period. Hybrid rice is generally fairly sensitive to temperature and light, particularly during the heading and blossoming season when it can be particularly hurt by cold dew winds. For most hybrid combinations being promoted over wide areas in the province today, full heading has to occur before the end of September. Thus, it may be sown in early July and transplanted in late July or early August in south central prefectures to form heads in late September and ripen in early November. In the north and in mountain regions, sowing has to be advanced to late June or early July, with transplanting done at the end of July to assure full heading before 25 September in order to avoid the cold dew winds. (2) Numbers of seedlings have to be appropriately increased so as to get more tillers early in the season so as to assure a sufficient number of panicles for high yields. Generally speaking, between 60,000 and 80,000 basic seedlings per mu should be planted in fertile fields, and in fields of less than moderate fertility between 80,000 and 100,000 basic seedlings (including tillers) per mu should be planted. Not all hybrid rice tiller form panicles, but the panicle formation rate from early seasoning tillering is high; consequently, in order to get a substantial amount of tillering during the early season, in addition to making sure to sow lightly to nurture sturdy seedlings, open field care during the early season is very important. The experience of high yield units is to put down sufficient base fertilizer, and then within 3 to 5 days after transplanting to apply urea at the rate of 12 to 15 jin per mu. After the seedlings green up, irrigation should be done to keep the seedlings moist to promote much early season tillering. (3) Intensification of late season care to prevent premature deterioration. After the fields have been sunned and water returned to them, if plant condition warrants, a top dressing of panicle fertilizer should be applied. Examination of plants has shown that when panicle fertilizer is applied around the 13 leaf stage, the heading rate is higher than when it is applied at the 14 leaf stafe, for an increase in yields of about 5 percent per mu. When panicles rupture and growth of the standing grain is unsatisfactory, a spraying should be given using phosphate fertilizer and urea. Experiments show that leaf spraying with phosphate fertilizer produces yield increases of form 3 to 5 percent as compared with no spraying with phosphate fertilizer, and that spraying twice produces 4 to 6 percent greater yields than spraying once. In water management, fields must be kept moist and premature withdrawal of water strictly guarded against. Withdrawal of water 7 days before harvesting produces 20 to 30 percent greater yields than withdrawal of water 12 days before harvesting.

CSO: 4007/476

BRIEFS

PROCUREMENT WORK--The total amount of agricultural and sideline products procured in Guangdong Province in the first half of this year was 2.11 billion yuan, which was 11.8 percent more than in the corresponding period of last year. [HK110509 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 6 Aug 82]

BUMPER SOYBEAN HARVEST--Guangdong Province reaped a bumper soybean harvest this summer. The total soybean output in the province is 170,000 dan more than the same period last year, which is an 11.8 percent increase. The average output per mu is 137 jin, which is 14 jin more than the same period last year. Both the total output and the per mu output figures have set new records. The increase has been due to the expansion of the area of land that has been used in cultivating soybeans and to scientific farming. [Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 9 Aug 82]

HYBRID EARLY RICE--Guangdong Province reaped a bumper harvest from 2.8048 million mu of hybrid early rice and per-mu yield was about 100 jin more than the per-mu yield of conventional early rice. The area sown with hybrid early rice this year was 150 percent more than in the corresponding period of last year. [HK111355 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 8 Aug 82]

PREFECTURE GRAIN PRICES--Since the summer harvest, the grain prices in Zhanjiang Prefecture have dropped. The negotiated price of rice sold by the grain stations on the Leizhou Peninsula, the Jiangjiang Plain and the bank of the Moyangjiang River has fallen from .38 yuan a jin to .35 yuan a jin. The price of every 100 jin of unhulled rice sold by the agricultural market has been reduced by 3 to 4 yuan. The per-jin price of sweet potatoes is .04 to .05 yuan. The prices of miscellaneous food grains and beans have also dropped accordingly. The gradual reduction in grain prices in the prefecture is the result of ample supplies of grain. [Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 8 Aug 82]

GOOD PEANUT HARVEST--Guangdong Province has completed the harvesting of the 5.31 million mu of spring-sown peanuts. According to statistics compiled by relevant departments, total output of peanuts is some 10.27 million dan, 4.9 percent more than in the corresponding period of last year. Total output and per-mu yield have exceeded the previous highest levels. The province has increased peanut production for 4 consecutive years. [Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 8 Aug 82]

SUGAR OUTPUT--As of early August, Guangdong had turned in to the state 630,000 dun of sugar, overfulfilling its quota by 90,000 dun and registering a 57.5 percent increase compared with last year. In the 1981-82 sugar season, Guangdong's total sugar output was 1.28 million dun. [OW130805 Beijing XINHUA Domestic Service in Chinese 0114 GMT 11 Aug 82]

GUANGDONG, GUANGXI RICE HARVEST--Beijing, 4 Aug (XINHUA)--Guangdong Province, one of China's major rice producers reports a harvest of 8.25 million tons of early rice this year, 350,000 tons more than in 1981. Per-hectare rice yield was 4.38 tons, 262.5 kilograms more than last year's figure. The neighboring Guangxi Zhuang Autonomous Region, also a major rice producing area, expects to harvest about 400,000 tons more early rice on 1.2 million hectares of fields this year than last. Heavy rains hit Guangdong between mid-May and June and affected 166,000 hectares of rice fields. In Guangxi also, the paddy fields of 19 countries in the northern and eastern parts were innundated due to the heavy downpours. The good harvest, provincial and regional agricultural departments said, represented an achievement made despite waterlogging, and is due to the institution of the job responsibility system, popularization of fine rice strains and transformation of low-yield fields. [Text] [Beijing XINHUA in English 0727 GMT 4 Aug 82]

EARLY RICE HARVEST--According to a preliminary estimate, Guangdong Province has reaped a bumper harvest of early rice with total output of 16.5 billion jin, an increase of more than 700 million jin compared to 1980. The per unit yield is 584 jin, an increase of 35 jin. [Excerpt] [Beijing RENMIN RIBAO 4 Aug 82 p 1]

CSO: 4007/570

BRIEFS

INDUSTRIAL CROP PRODUCTION--Despite natural disasters, Guangxi region reaped a bumper harvest of industrial crops in the first half of this year. According to statistics, by the end of June the region had procured some 16,200 dan of pineapples, which was 39.12 percent more than in the first half of last year; some 86,000 dan of bananas, which was 68.7 percent more than in the corresponding period of last year; and some 65,300 dan of tea, which was 21.72 percent more than in the same period of last year. [HK110833 Nanning Guangxi Regional Service in Mandarin 1130 GMT 8 Aug 82]

EARLY RICE HARVEST--Guangxi Zhuang Autonomous Region reaped more than 18 million mu of early rice, with total output projected to be about 800 million jin more than 1981. The most obvious characteristic of this year's early rice production is a balanced increase of output over a large area. Of the region's 8 prefectures, 7 increased output. SUMMER GRAIN PROCUREMENT OVERFULFILLED

Shijiazhuang HEBEI RIBAO in Chinese 1 Jul 82 p 1

[Article: "Province's Summer Grain Procurement and Warehousing In Full Tide. Large and Small Trucks Fully Loaded With Summer Grain Head From All Directions Toward State Granaries. Twnety-nine Counties (or Municipalities) Have Fulfilled or Overfulfilled Their Summer Grain Procurement Quotas"]

[Text] The province's summer grain procurement and warehousing is in full tide. For days on end, highways and main thoroughfares have been a bustling scene of large and small trucks fully loaded with summer grain moving in an endless stream from all directions toward state granaries. They have averaged deposits in granaries of more than 100 million jin daily. As of 29 June, the summer grain procured and stored in granaries amounted to 54.3 percent of plan. Cangzhou Prefecture has overfulfilled this year's summer grain procurement quota, the amount going into granaries being 2.7 times that of the same period last year. Quotas were fulfilled 40 days earlier than last year. Handan Prefecture and Shijiazhuang City have fulfilled more than 85 percent of their summer grain state procurement quotas, and the pace of procurement and warehousing in Hengshui and Baoding prefectures is notably faster than during the same period last year. After nine counties including Nanpi, Linzhang, Handan, and Ji fulfilled their summer grain state procurement quotas, the counties of Daming, Wei, Jize, Guangping, Cheng'an, Ci, Wuan, Xinhe, Pingshan, Qingyuan, Anci, Wenan, Dacheng, Xian, Hejian, Dongguan, Wuqian, Mengcun, Suning, and Cangzhou City fulfilled and overfulfilled their summer grain state procurement quotas.

This year the province's summer grain crops encountered severe, protracted drought, and during the late stage, hot dry winds and aphid pests occurred. However, thanks to the tremendous power of the party's policies the further perfection and completion of production responsibility systems, and the combat against disaster and painstaking care of the broad masses, damage caused by the disasters was reduced. Cangzhou Prefecture located in the Heilonggang Basin has a smaller summer harvest area than last year. The masses praise the party's policies as being good, and eagerly sell patriotic grain to the state. In order to win the battle of summer grain procurement, leaders at all levels have taken the initiative for all of this year, and for the next 2 years, have genuinely strengthened leadership, and have diligently implemented existing contract procurement policies, which have won the confidence of the people.

Grain departments have increased the number of network outlets to get grain into granaries and have lengthened work hours. Some places have transferred personnel, and have gone into production teams with scales, containers, and cash to make onsite examinations of quality, using every available means to accomodate the masses in making sales, thereby accelerating the pace of grain getting into granaries.

IMPROVED MANAGEMENT, SCIENTIFIC FARMING CREDITED FOR BUMPER HARVEST

Shijiazhuang HEBEI RIBAO in Chinese 28 Jun 82 p 1

[Article: "Qiu County Conquers Drought, Insect Pests, and Wind Disasters To Win Bumper Wheat Harvest. Ninety Percent Increase in Gross Output Over Last Year, and Yields Per Unit of Area Almost Double Last Year's"]

[Text] During this time of the wheat harvest, heartening news of a bumper harvest has been relayed from Qiu County located in the Heilonggang Basin. The county's 175,000 mu of wheatfields have delivered an output of 35 million jin, a 90 percent increase over last year, and yields per unit of area amounted to 200 jin, almost double last year's.

Use of the spirit of the Central Committee Rural Work Conference to solve crucial problems currently existing in rural work is the most important reason for the bumper summer harvest that this county reaped. In this county, 98 percent of production teams have instituted responsibility systems whereby peasant households assume full responsibility for task completion. Nevertheless, two problems were fairly prominent. One was that many production team groups were in a state of paralysis or semi-paralysis; the second was that pump well management was in disarray, and peasants found it difficult to water their fields. In view of these circumstances, last winter and this spring, firm action was taken throughout the county to reorganize grassroots level groups and pump well management systems of responsibility. Groups that had been reorganized and readjusted made full use of their accumulated skills. In the realm of pump well management, everything was under the centralized management of production brigades, production teams, or work teams, with specific persons designated responsible in the practice of different forms of responsibility systems, which greatly increased the pump well effective watering rate. Most of the county's wheatfields were watered more than twice, and in many production teams watering was done four or five times. Watering was done on a cumulative 440,000 mu throughout the county, making it an all time high year for area of wheatfields watered.

Spread of science and technology and institution of scientific farming was yet another important reason for this county's being able to harvest a bumper wheat crop this year. In view of the new circumstances whereby individual households assumed full responsibility for tasks, agricultural technicians and commune members in most communes signed agreements linking output to wheat growing techniques. During different stages of wheat growth, agricultural science and technology units would use wired broadcasts, disseminate printed materials, and give on-site demonstrations to impart scientific techniques and rotationally train more than 30,000 mainstay cadres in techniques. They emphasized more than in previous years three methods of scientific crop care. One was increased fertilization with phosphate; second was a good job of winter irrigation and proper postponement of irrigation for greening up; and third was fairly effective prevention and control of wheat aphid and hot dry wind damage.

BUMPER WHEAT HARVESTS REPORTED IN TWO PREFECTURES

Shijiazhuang HEBEI RIBAO in Chinese 2 Jul 82 p 1

[Article: "Cangzhou and Hengshui Prefectures Win Bumper Wheat Harvest. Diligent Perfection of Production Responsibility Systems and Tenacious Struggle Against Severe Drought"]

[Text] Canzhou Prefecture, located in the middle and lower reaches of Heilonggang, has relayed joyous news about a bumper summer harvest. Statistics from prefectural units concerned show that despite 4 consecutive years of drought and a 20 percent reduction from last year in the prefecture's wheat growing area, total wheat output has increased 40 percent and yields per unit of area have increased more than 60 percent this year. As of 29 June, the prefecture had already overfulfilled its summer state procurement quota.

Beginning with the fight against drought to plant wheat last fall, Cangzhou Prefecture promoted various forms of production responsiblity systems, which sparked the energies of cadres and commune members. Throughout the prefecture, soil moisture was made on more than 3 million mu of wheat growing area, and quality of sowing was such as had not been seen for many a year. Last winter and this spring, all counties and communes took a firm grip on the perfection of responsibility systems, helped contracting households solve real difficulties, brought into full play the initiative of both collectives and commune members, and gave impetus to the launching of a struggle against drought. Throughout the prefecture a general mobilization of males, females, the old and the young took place, and round the clock all out efforts were made to sink wells and water the wheat. Within a several month period, funds raised for water conservancy alone amounted to more than 38.6 million yuan, including more than 17.7 million contributed by commune members themselves. In fighting drought to water the wheat, for more than 85 percent of the pump wells in the prefecture, responsibility systems were applied. In Nanpi County, where a good job was done, various forms of contracting were done for more than 2,900 pump wells and associated equipment. Watering of fields from deep wells increased from 15 to 33 mu daily, and watering from shallow wells rose from 7 mu to 14 mu daily while watering costs dropped 30 percent. In addition, throughout the prefecture more than 230 new deep pump wells, more than 3,500 shallow pump wells, and more than 9,000 vacuum wells were sunk. In addition, more than 60,000 hand pump vacuum wells were added. This plus the use of some water diverted from the Huang. He permitted the watering of a total wheatfield area in the prefecture of more than 3.7 million mu, 1 million mu more than during the same period last year. All counties and communes stabilized and perfected production responsiblity systems, which they developed toward the linking of output to technology to promote scientific management of the wheat and scientific use of water. In some communes and brigades new techniques of "shallow application of two fertilizers," use of brackish water, and regionalization of fine varieties were promoted over wide areas to make for a bumper wheat harvest.

Hengshui Prefecture conquered serious drought to win a bumper wheat harvest this year. Despite a 700,000 reduction from last year in the wheat growing area, total output increased almost 30 percent over last year.

This prefecture has had drought for 4 consecutive years. Under these circumstances, beginning with wheat planting last year, all levels of leadership cadres throughout the prefecture went deep into the countryside to publicize pertinent documents of the Central Committee, to study new circumstances, to solve new problems, to focus principal efforts on the perfection of various production responsibility systems, and to emphasize establishment and perfection of pump well management responsibility systems so that pump wells and such water conservancy facilities would find full use. In addition, commune and brigade collectives and individuals used every available means to accumulate funds to sink more than 3,200 pump wells of various kinds, and to repair more than 3,400 defective or broken wells. Some counties used water diverted from the Huang He, thereby being able to water 700,000 mu more wheat this year than last. The Fucheng County CCP Committee and county government selected 100 comrades with rural work experience who understood policies to organize work teams to go from village to village to help perfect production responsibility systems and to spur on the fight against drought for a bumper harvest. Every one of the 22 communes in the county doubled its summer output. Throughout the prefecture, scientific management of wheat was also better than in former years. By way of spreading scientific techniques, in addition to emphasizing the training of farm technicians, all the counties and communes in the prefecture ran a total of 657 farm technology training classes, 427 special seminars on wheat management techniques, more than 490,000 people receiving training. This brought about the scientific watering of fields, application of top dressings of fertilizer at the right time and in the right amount, and a change particularly from the former spreading of phosphate fertilizer all over the ground to shallow application of a mixture of phosphate and nitrogenous fertilizer for very good results.

NOTICE ISSUED ON PESTICIDE CONTROL

Shijiazhuang HEBEI RIBAO in Chinese 28 Jun 82 p 1

[Article: "Intensify Pesticide Management To Strictly Guard Against Accidental Poisoning. Relevant Provincial Departments Issue Joint Notice"]

[Text] Recently the Provincial Public Security Department, the Health Bureau, the Agricultural Bureau, the Supply and Marketing Administration, and the Chemical Industry Bureau issued a joint notice requiring all jurisdictions to intensify pesticide management to strictly guard against accidental poisonings.

The notice said that the farflung rural villages of the province have entered a period of eradication of agricultural crop disease and insect pests, and all jurisdictions are to emphasize propaganda and education in the safe use of pesticides. In rural villages, production teams should designate a person with specific responsibility or concurrent responsibility for the safekeeping and use of pesticides. Persons who have not undergone training or lack safety knowledge shall not be permitted to use or store pesticides. All pesticides must be centrally purchased by production teams or specialized teams, and their use is to be strictly managed. All regulations pertaining to pesticide use are to be strictly observed. All pesticide containers must bear complete and firmly attached lables as well as detailed instructions for use. Those not meeting these aforestated requirements are, without exception, not to be permitted to leave the plant where they are manufactured. Mixing of pesticides, or soaking and mixing seeds in them, is to be done far away from drinking water sources, cattle feed sites, messhalls, granaries, and foodstuffs. When used, protective clothing and equipment is to be worn, and required antidotes are to be carried. It is forbidden to spray pesticides during noon heat or with exposed arms or body. Fields and orchards that have been sprayed with insecticides should be clearly posted during the danger period, and both people and livestock kept from entering.

The notice said that in the work of preventing and controlling farm crop diseases and insect pests, it is necessary to stick to the principle of "centralized organization of prevention and control," instituting centralized inspections for insects, centralized purchases of pesticides, centralized storage, centralized mixing of pesticides, and centralized treatment of crops done by specialized teams, fees being levied on separate households on the basis of the area covered in a treatment system of "five centralized and one separate." This is a fundamental reversal of separate household purchases of pesticides, keeping of pesticides, and use of pesticides so as to eliminate unsafe factors. It is strictly prohibited to sell pesticides without authorization or to resell insecticides privately at a profit. For all chemical pesticides with the exception of benzene hexachloride, DDT, and dichlorvos, which may be sold by grassroots supply and marketing units for use in public health, all other pesticides must be supplied soley by centralized means of production supply units. Purchases of pesticides must be done against certificates issued by production brigades. Responsibility will be fixed for violators.

FIGHT AGAINST BOLLWORMS OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 28 Jun 82 p 1

[Article: "Handan Prefecture Goes All Out To Eliminate Cotton Bollworms. All Levels of Leaders Go Into Cottonfields, and All Departments Make Concerted Effort"]

[Text] In order to insure normal cotton growth, Handan Prefecture leadership cadres at all levels have gone into the cottonfields to lead the masses in an all out effort to eliminate second generation bollworms.

According to most recent monitoring reports, second generation bollworms have broken out everywhere in this prefecture 10 days earlier than in most years, and ova are from 8 to 10 times more numerous than in most years. Never has there been a bollworm situation as severe as this one during the same period in this prefecture. In order to eliminate them at once, the Provincial CCP Committee and government administrative offices issued a bollworm prevention and control report in early June, and on 16 June they held an on-site meeting at Qiu County at which all levels of all units were asked to establish personal responsibility systems, take genuine control of the bollworm situation, pick the proper time for combat, and arouse the masses to make an all out effort at elimination. Qiu County, which acted relatively early, fielded 20,000 people and used 18,000 pieces of spraying apparatus. By 16 June it had cleared 110,000 mu to bring the bollworms virtually under control. Comrades in charge at the Linzhang County CCP Committee Standing Committee, the deputy county magistrate, and the chairman and deputy chairman of the representative assembly, as well as those in charge of departments, offices, committees, and bureaus went to villages and communes in an all out effort to direct control of the bollworms, An overwhelming majority of communes and brigades in the prefecture instituted centralized monitoring and reporting, centralized purchases of pesticides, centralized formulation of pesticides, centralized standards, and centralized times, the work of eliminating bollworms being done by separate households. They used a combination of highly effective pesticides and conventional pesticides, native methods and foreign methods, a combination of powders and emulsions, and a combination of biological prevention and control and chemical prevention and control. Farm technicians at all levels both promptly and accurately monitored and reported on the bollworm situation and also used diverse methods to get bollworm control techniques into the hands of the myriad households. Supply and marketing units persevered in gearing to the needs of production and service to agriculture, lengthening hours of operation and taking the initiative in sending pesticide apparatus to production teams and households. According to 10 June statistics, prefecture supply and marketing cooperatives had already sent to the countryside more than 5,700 tons of pesticide and more than 66,000 pieces of pesticide equipment. As of 17 June, more than 860,000 mu had been cleared in the prefecture, amounting to 80 percent of the area of bollworm occurrence.

LIVESTOCK DEVELOPMENT--After production readjustment between agriculture and livestock, Heilongjiang Province has made great progress in developing livestock. The province has zoned Anda County and Dorbod Monggol Autonomous County as livestock areas and 11 other counties in western Heilongjiang including Longjiang, Fuyu, Gannan and Tailai, as half agricultural and half livestock areas. Cattle and sheep sold by the 13 counties to the state account for 48 percent of the total number in the province and wool output, 50 percent of the provincial volume. According to statistics compiled at the end of June, the province scored a 600-700 percent increase in raising milk cows over the former figure and a 10-fold increase in raising cattle and horses. It also scored a 75 percent increase in raising milk cows over 1978's figure and a 100 percent increase in raising sheep, as well as scoring a 100 percent increase in meat cattle sold to the state over 1978's figure, a 150 percent increase in fresh milk and a 200 percent increase in sheep's wool. In 1981, per capita income from livestock undertakings scored a 40 percent increase over the previous peak. [SK141206 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 13 Aug 82]

DAIRY PRODUCT OUTPUT--Since the third plenary session of the 11th CPC Central Committee, Heilongjiang Province has scored an over 37 percent increase in dairy industrial production each year. In 1981, the province surpassed the 1978 output by 140 percent. Over the past 3 years, the province has accumulated over 27 million yuan for the state. As of July this year, the province had 100,000 head of milk cows, a more than 100 percent increase over the 1981 figure. Through technical renovations, dairy farms across the province have upgraded their daily capacity in processing fresh milk from over 300 tons to over 600 tons. [Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 13 Aug 82]

COMMUNE AND BRIGADE-RUN ENTERPRISES--Since the third plenary session of the 11th CPC Central Committee, Heilongjiang Province has made great progress in developing commune and brigade-run enterprises. According to statistics compiled at the end of 1981, the province had over 21,000 enterprises of this kind, which employed over 544,000 people. Over the past 3 years, the province has scored a 14.4 percent increase in the enterprise number each year, has handed over 120 million yuan of taxes to the state, has conserved 450 million yuan for collective accumulation and has scored an over 800 million yuan increase for commune member incomes. At present, the province has 3,600 production networks and centers that have achieved over 300 million yuan of output value over the past 3 years. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 13 Aug 82]

TAHE COUNTY RAINFALL--Owing to a 115-mm torrential rainfall on 8 August, residents of 1,500 households in Tahe County, Heilongjiang Province, were plagued with torrents of water rushing down the mountains. According to a report made by rescue teams dispatched by the county people's government, there were no casualties thanks to timely rescue operations.
